## Bode Plot Screen

The **Bode Plot Screen** allows the measurement of a servo loop and graphs the open loop response. A Bode Plot is by far the most common means used to measure and understand the behavior of a control loop. **KMotion** contains advanced built-in features to allow rapid Bode Plot measurement and display. The current PID and IIR Filter transfer functions may also be superimposed and graphed.

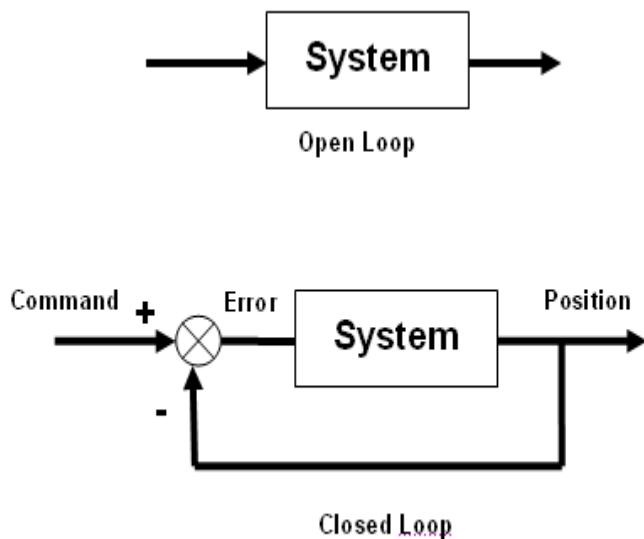

A Bode Plot is a plot of magnitude and phase of a system with respect to frequency. Any linear system that is driven by a sinusoidal input for a long time, will output a sinusoidal signal of the same frequency. The output signal may be shifted in phase and of a different magnitude than the input. A Bode plot is a graph of both the change in phase and the relative change in magnitude (expressed in decibels, db), as a function of frequency.

A Bode plot is a useful tool used to examine the stability of a servo feedback loop. If a system has an open loop gain of -1 (magnitude of 0 db and phase of -180 degrees), then if it is placed into a negative feedback loop, it will become unstable and oscillate. Because a system's gain and phase vary as function of frequency, if the system has a magnitude of 0db and phase of -180 degrees at *any frequency* it will be unstable and oscillate at that frequency. The way to avoid an unstable system is to avoid having simultaneous conditions of 0db and -180 degrees occur at any frequency. Where the magnitude of the system is 0db the amount that the phase is different from -180 degrees

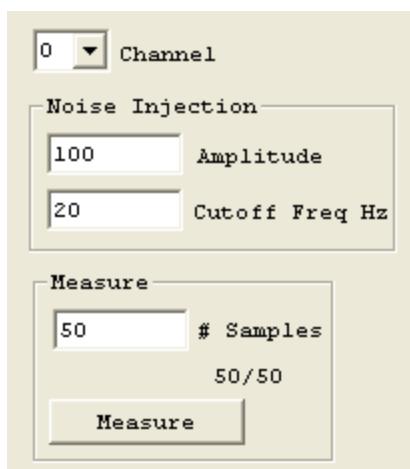

is called the *phase margin*. The larger the phase margin the more stable the system. Similarly where the phase is -180 degrees the amount that the magnitude is different from 0db is called the *gain margin*. Again the larger the gain margin, the more stable the system. As a general rule of thumb, for a system to be reasonably stable it should have a phase margin of at least 30 degrees and a gain margin of at least 3 db.

The Bode Plot Screen attempts to identify and measure the 0 db crossover frequency (the first point where the open loop magnitude becomes less than 1, often defined as the system bandwidth, 228 Hz on the example above), the gain and phase margins, and one or two sharp peaks in the magnitude data after the crossover. Some mechanical systems have sharp resonant peaks that may cause the system to go unstable if these peaks approach the 0 db line and have phase near -180 degrees. A notch filter placed at these frequencies may increase performance. The measurements are displayed under the graph as shown below.

0db Cross Over:228Hz Gain Margin:7db Phase Margin:48deg Peak:1535Hz

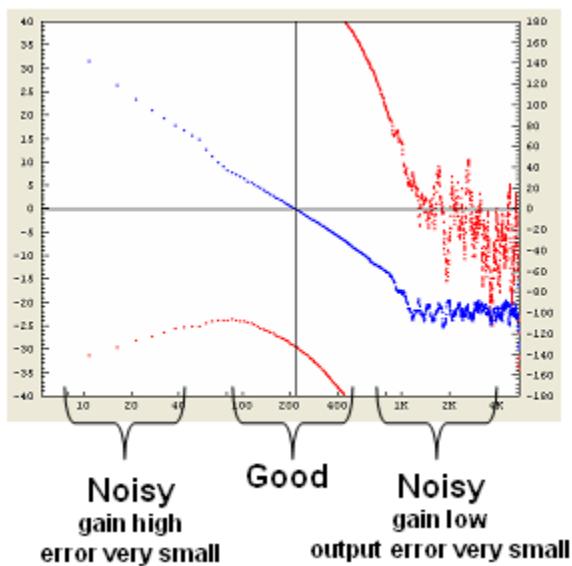

The most direct method for obtaining the open loop response is to break the servo loop open, inject a signal into the system and measure the output. However, this is usually impractical as most systems will run out of their linear range if driven in an open loop manner. **KMotion** operates the servo loop in its normal closed loop form, injects a command signal, measures the position response, and mathematically derives the open loop response. This does require that the servo loop function in some form as a stable closed loop servo *before* a measurement may be made. Performance is not a requirement so low gains might be used to obtain an initial stable system.

To perform a *Bode Plot* Measurement: select the *channel* to measure, select the desired [Amplitude and Cutoff Frequency](#) for the stimulus to be injected, select the # of samples to average, and depress the *Measure* Pushbutton. All current Configuration Parameters (from the [Configuration Screen](#)), Tuning Parameters (from the [Step Response Screen](#)), and Filter Parameters (from the [IIR Filter Screen](#)) will be downloaded, the selected Axis channel will be enabled, and the measurement will begin.

While the measurement is in progress the number of samples acquired will be displayed and the *Measure* Pushbutton will change to a *Stop* Pushbutton. Pushing the Stop button will stop acquiring data after the current sample is complete.

Depending on the type of plot requested (either Time Domain or Frequency Domain) either the last acquired time domain measurement will be displayed or the average all the frequency domain measurement so far acquired will be displayed.

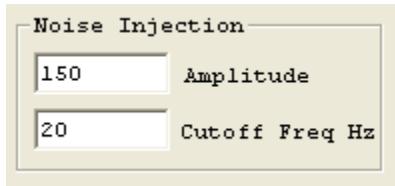

Unfortunately Bode Plots often have regions that are very noisy. But fortunately these are almost always in regions that are not important to us. At frequencies where the open loop gain is very high (usually at low frequencies), the servo loop performs very well, and the *Position* closely matches the *Command* signal. In this case, the calculation of the *Error* signal (see above) is calculated by taking the difference between two nearly equal values. A small error in Position measurement will then result in a relatively large error in the calculated error value. Similarly, when the system has a very low gain (usually at high frequencies), the position signal is very small and often highly influenced by noise, or if an encoder is used, by encoder resolution. The regions of interest in order to determine system stability, are where the open loop gain is near 0db and the measurements

are normally very accurate.

Additionally, instead of injecting sine waves at various frequencies individually, **KMotion** uses a technique where a random noise signal that is rich in *many* frequencies is injected. Using a method involving an FFT (Fast Fourier Transform) of the input and output, the entire frequency response may be obtained at once.

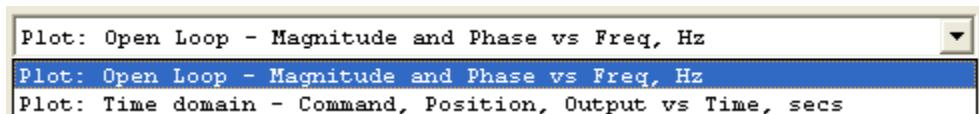

Bode Plot analysis is fundamentally based on the assumption that the system being analyzed is *linear*. Linear in this context means that any signal injected into a system that provides a response, might be broken into parts, each piece injected separately, and all the resulting responses when summed would equal the original response. If a system being measured does not meet this criteria

then the result is basically useless and meaningless. Masses, Springs, Dampers, Inductors, Resistors, Capacitors, and all combinations thereof are examples of devices which produce very linear effects. Static friction, Saturation, and Encoder count quantization, are examples of non-linear effects.

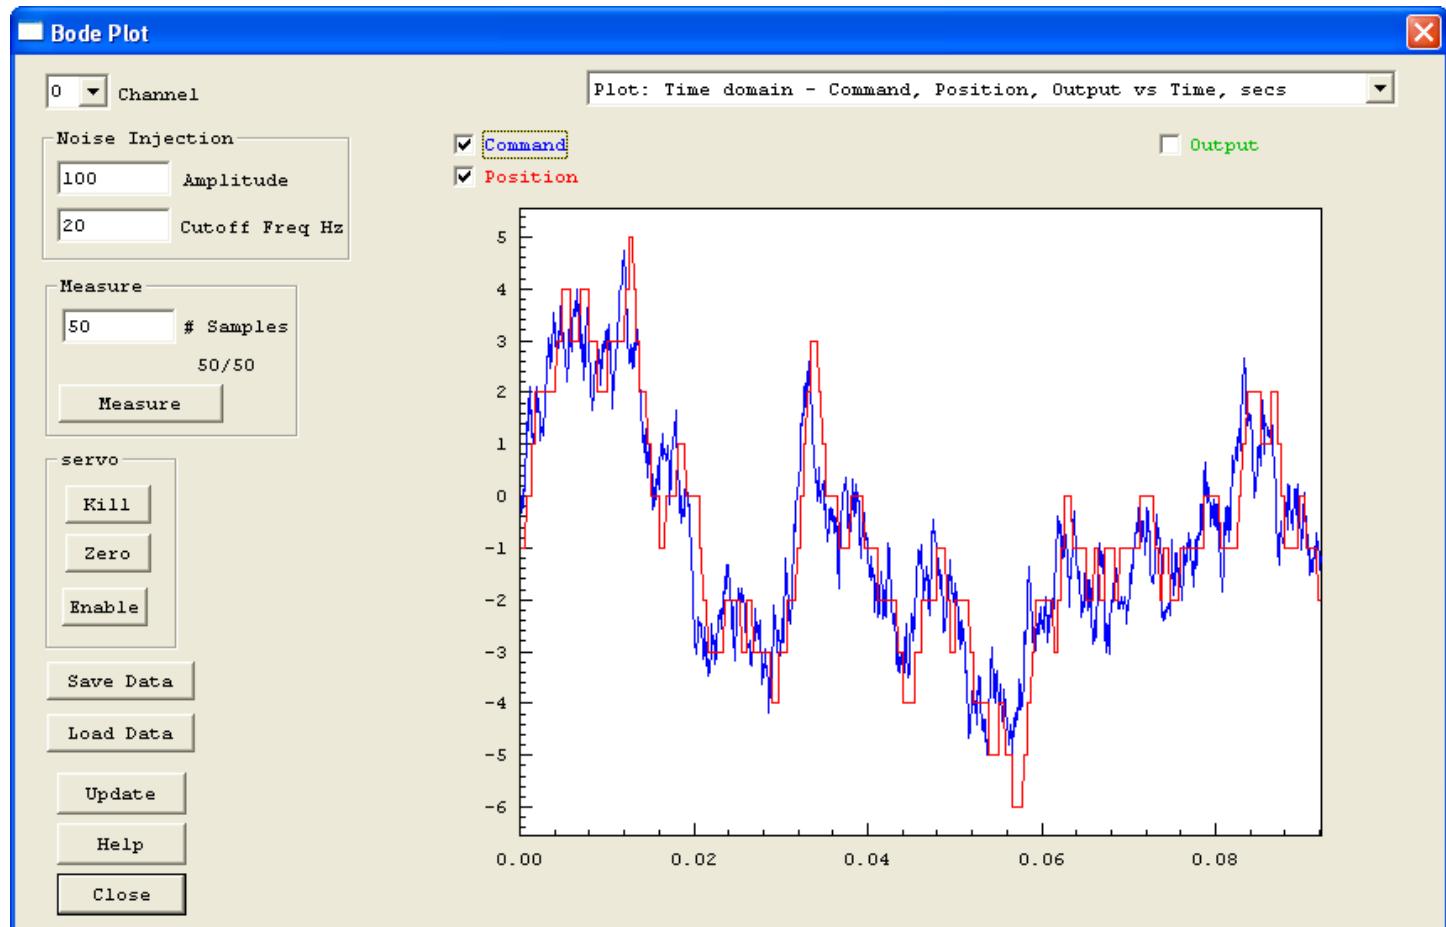

It is therefore very important to verify that while the system is being measured that it is operating in its linear range. This usually entails that the system isn't being driven too hard (or too fast), so that the drive to the system (*Output*) is not reaching saturation. Additionally, it is important to verify that the system is being driven sufficiently hard (or slowly enough) that a measurable *Position* change is being observed. The *Noise Injection Amplitude* and *Cutoff Frequency* should be adjusted to optimize these conditions. *Noise Amplitude* has the same units as *Position Measurement*. It should be noted that setting the *Cutoff Frequency* very low, may reduce the high frequency stimulation to the system to such a point that the higher frequency measurements are invalid or very noisy.

The Bode Plot Screen allows the measurement data to be viewed in the *time domain* in order to check the signal amplitudes so that the optimal signal levels may be used in order to minimize the non-linear effects of saturation and quantization. Select the Plot Type drop down list shown below to switch between frequency domain and time domain displays.

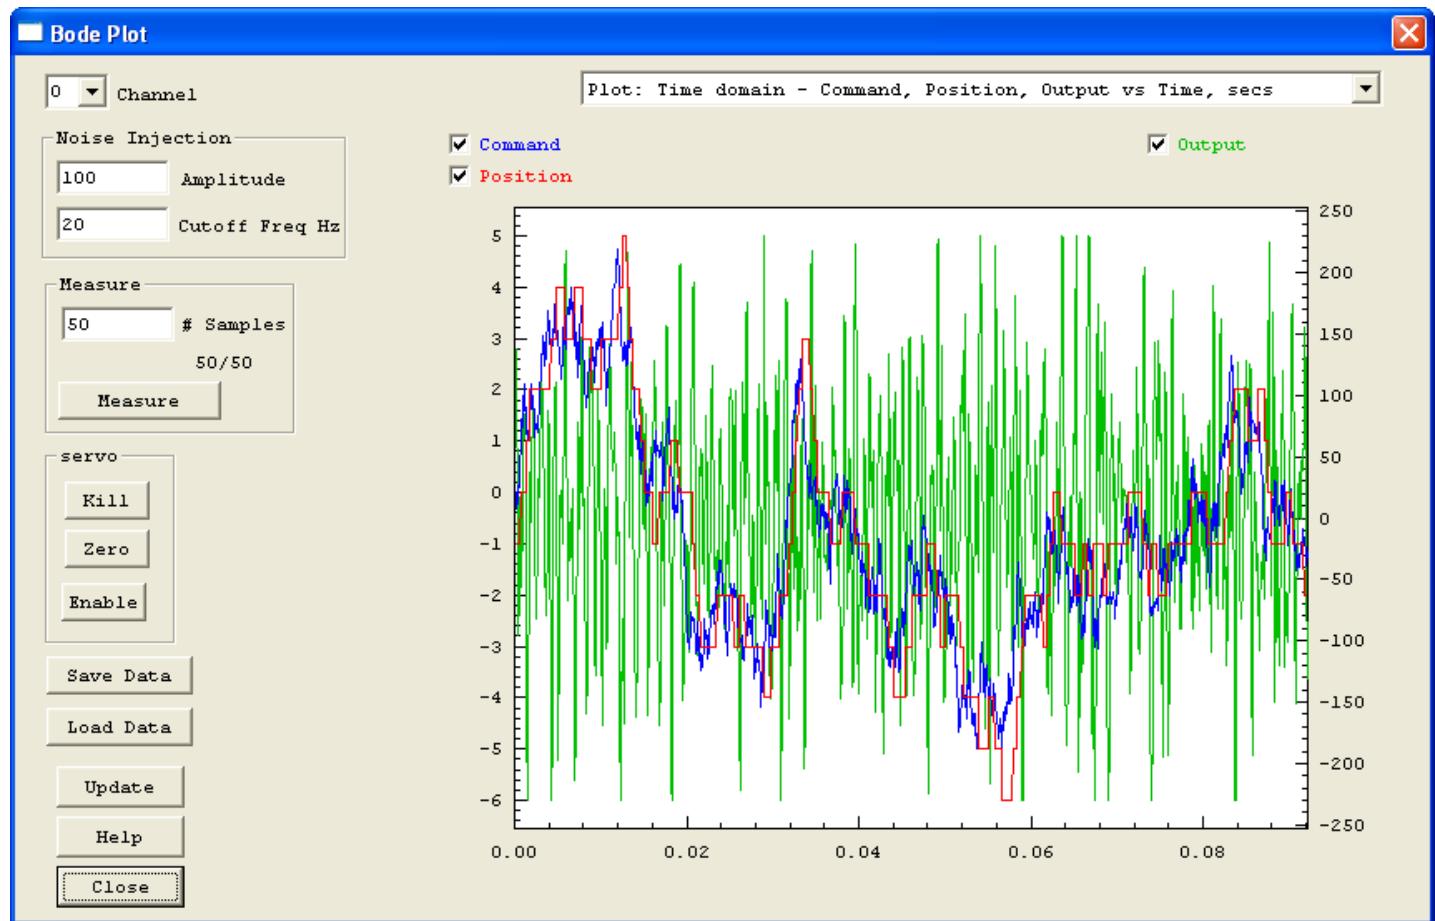

A typical time domain measurement is shown below. The *blue* graph shows the random stimulus to the system. The *red* graph shows the system's response, which in this example is the output of an encoder. Note that the position is quantized to integer counts and has a range of approximately 10 counts. This is nearly the minimum number of counts to expect a reasonable Bode Plot measurement. A larger range of encoder counts could be obtained by driving the system harder by increasing the Noise Injection Amplitude, provided there is additional output drive available.

The graphs below include the output drive signal shown in green. Note that the output drive is on the verge of saturating at the maximum allowed output value (example is from a 3 phase brushless motor, maximum allowed PWM counts of 230). This shows that we are driving the system as hard as possible without saturating in order to obtain the most accurate measurement.

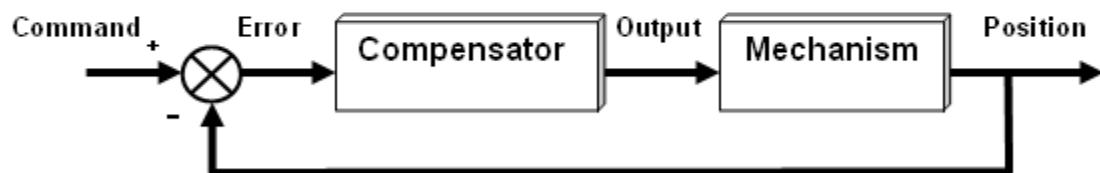

Another means of improving the measurement accuracy (as well as servo performance in general) is obviously to increase the encoder resolution if economically or otherwise feasible.

### Compensator Response

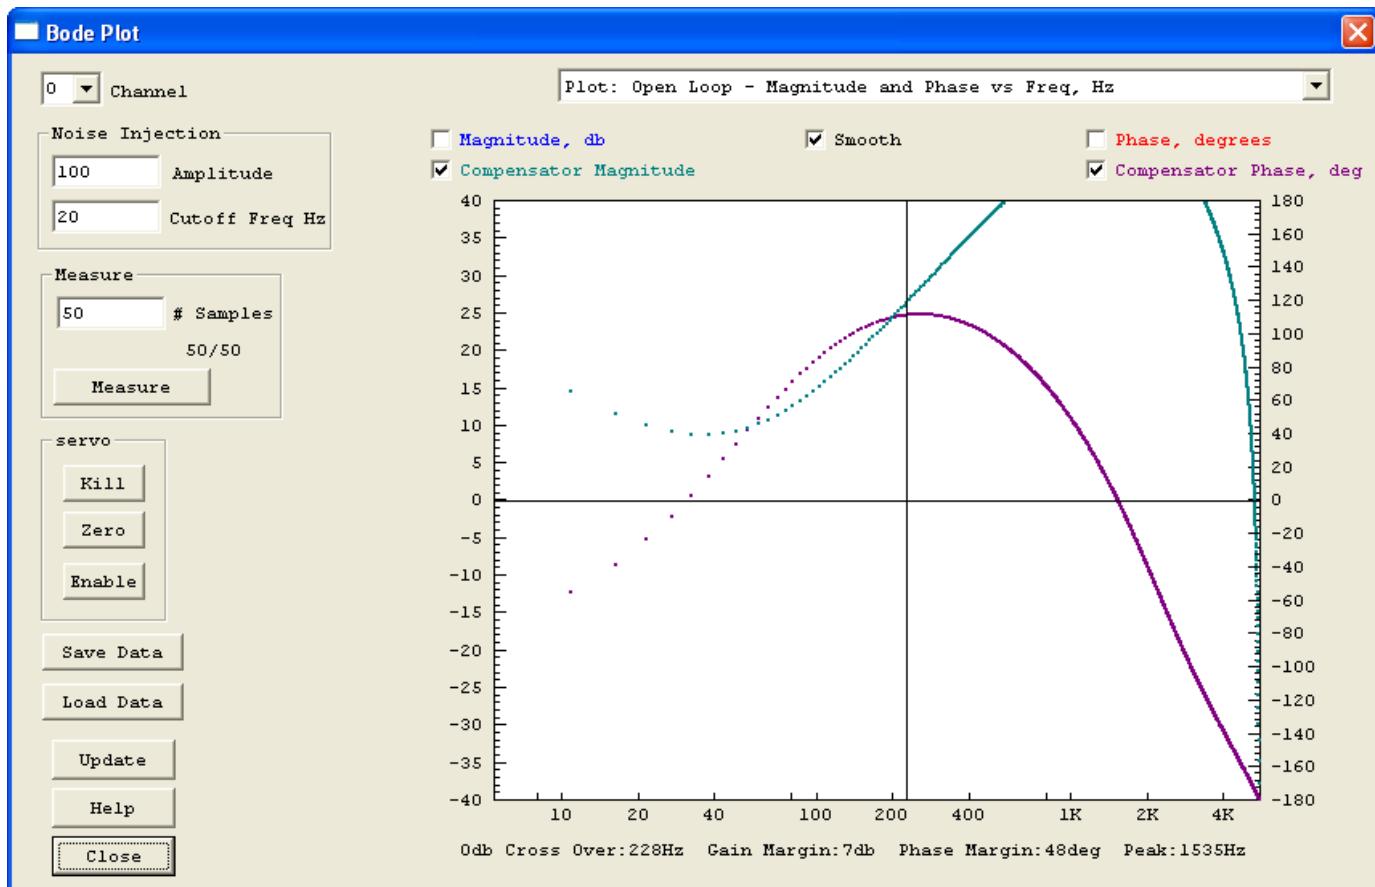

*KMotion Compensator*

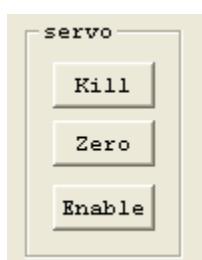

*Complete Closed Loop Servo*

The *Bode Plot Screen* is also capable of graphing a *Bode Plot* of the combined PID and IIR Filters. This is often referred to as the *Compensator* for the system. The Cyan graph shows the magnitude of the compensator and the violet graph shows the phase of the compensator. Notice that in this example the maximum phase has been adjusted to match the 0 db crossover frequency of the system (~ 233 Hz) to maximize the system phase margin.

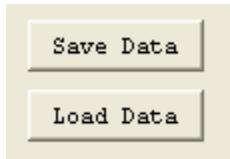

## Axis Control

The Axis Control buttons are present to conveniently disable (Kill), Zero, or Enable an axis. If the axis becomes unstable (possible due to a gain setting too high), the Kill button may be used to disable the axis, the gain might then be reduced, and then the axis may be enabled. The Enable button downloads all parameters from all screens before enabling the axis in the same manner as the [Measure](#) button described above.

*Note for brushless output modes that commutate the motor based on the current position, Zeroing the position may adversely affect the commutation.*

## Save/Load Data

The Save/Load Data buttons allow the captured Bode Plot to be saved to a text file and re-loaded at a later time. The text file format also allows the data to be imported into some other program for display or analysis. The file format consists of one line of header followed by one line of 9 comma separated values, one line for each frequency. The values are:

1. Frequency in Hz
2. Input Stimulus - Real Part of complex number
3. Input Stimulus - Complex Part of complex number (always zero)
4. Measured Closed Loop Output - Real Part of complex number
5. Measured Closed Loop Output - Complex Part of complex number
6. Open loop Magnitude - in decibels
7. Open loop Phase - in degrees
8. Open loop Magnitude - in decibels - "smoothed"
9. Open loop Phase - in degrees - "smoothed"

Example of data file follows:

```
Freq,InputRe,InputIm,OutputRe,OutputIm,Mag,Phase,SmoothMag,SmoothPhase
0,2.329706e+007,0,2.344316e+007,0,44.10739,-180,0,0

## Update Pushbutton

The Update button may be used to update the displayed [compensator](#) graph if any parameters (on other screens) have been modified and not downloaded or otherwise acted upon. If Measure, Download, Step, Move, Save, Close, or Enable is used on this or the any other screen then this command is unnecessary, however if none of these commands is performed, then this button may be used to update the graph.

**KMotion's** G Code interpreter was derived from the Open Source EMC G Code Interpreter. Click here for the [EMC User Manual](#) (Only the G Code portions of the manual, Chapters 10-14 pertain to **KMotion** G Code)

Specially coded comments embedded within a GCode program may be used to issue **KMotion** Console Script commands directly to **KMotion**.

A comment in the form: (CMD,xxxxxx) will issue the command xxxxxx immediately to **KMotion** as soon as it is encountered by the Interpreter. Any **KMotion** command that does not generate a response may be used in this manner.

A comment in the form: (BUF,xxxxxx) will place the command xxxxxx into **KMotion's** coordinated motion buffer. Coordinated motion sequences are downloaded to a motion buffer within **KMotion** before they are executed. This guarantees smooth uninterrupted motion. The BUF command form allows a command to be inserted within the buffer so they are executed at an exact time within the motion sequence. Only the following **KMotion** Script commands may be used in this manner.

SetBitBuf, ClearBitBuf, SetStateBitBuf.

Additionally, a comment in the form: (MSG,xxxxxx) will pause GCode Execution and display a pop-up message window displaying the message xxxxxx.

or mm/min)

int n\_Samples);

void TriggerGather();

int CheckDoneGather();

*Analog I/O Functions:*

The screenshot shows a Windows application window titled "Program - C:\KMotion\K Motion\Init Motors 0 and 1.c". The window contains a code editor with the following C code:

```
#include "KMotionDef.h"

int main()
{
    ch0->Amp = 250;
    ch0->output_mode=MICROSTEP_MODE;
    ch0->Vel=70.0f;
    ch0->Accel=500.0f;
    ch0->Jerk =2000f;
    ch0->Lead=0.0f;
    EnableAxisDest(0,0);

    ch1->Amp = 250;
    ch1->output_mode=MICROSTEP_MODE;
    ch1->Vel=70.0f;
    ch1->Accel=500.0f;
    ch1->Jerk =2000f;
    ch1->Lead=0.0f;
    EnableAxisDest(1,0);

    DefineCoordSystem(0,1,-1,-1);

    return 0;
}
```

The status bar at the bottom of the window displays "No Errors, No Warnings". To the right of the code editor, there is a "Thread:" panel with seven radio buttons labeled 1 through 7, where button 5 is selected. The toolbar at the top of the window includes icons for New, Open, Save, Save As, Compile, Download, Run, Halt, and a multi-threading icon.

The **C Program Screen** allows the user to edit C language programs, compile, link, download, and run them within the **KMotion** board. C programs executing within the **KMotion** board have direct access to all the Motion, I/O, and other miscellaneous functions incorporated into **KMotion** System.

One of the most powerful features of the **KMotion** system is the ability for a user to compile and download native DSP programs and have them run in real time. Native DSP code runs faster than interpreted code. The TMS320C67x DSP that powers the **KMotion** system has hardware support for both 32 bit and 64 bit floating point math. Multiple threads (programs) may execute simultaneously (up to 7). The integrated C compiler allows with

a single pushbutton  to save, compile, link, download, and execute all within a fraction of a second. After programs have been developed and tested they may be flashed into memory and run stand alone with no host connection.

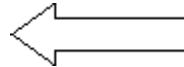

ADC(ch);  
DAC(ch, value);

*Power Amp Functions:*

```
void WritePWMR(int ch, int v);
void WritePWM(int ch, int v);
void Write3PH(int ch, float v,
double angle_in_cycles);
void Write4PH(int ch, float v,
double angle_in_cycles);
```

Other features of the **C Program Screen** include a rich text editor with syntax highlighting, keyword [drop down lists](#), [function tips](#), unlimited [undo/redo](#), and [Find/Replace with regular expressions](#).

See list on left for available constants and functions.

For a more details on the functions, see the [KMotionDef.h](#) header file. This file is normally included into a user program so that all accessible base functions and data structures are defined.

*Timer Functions:*

```
double Time_sec();
void WaitUntil(double
time_sec);
void Delay_sec(double sec);
double
WaitNextTimeSlice(void);
```

See [PC-DSP.h](#) for common definitions between the PC host and **KMotion** DSP.

*Axis Move Functions:*

```
void DisableAxis(int ch);
void EnableAxisDest(int ch,
double Dest);
void EnableAxis(int ch);
void Zero(int ch);
void Move(int ch, double x);
void MoveRel(int ch, double
dx);
int CheckDone(int ch);
void MoveXYZABC (double x,
double y, double z);
int CheckDoneXYZABC();
void DefineCoordSystem(int
axisx, int axisy,
int axisz, int axis a, int axis
b, int axis c);
```

*Digital I/O Functions:*

```
void SetBitDirection(int bit,  
int dir);  
int GetBitDirection(int bit);  
void SetBit(int bit);  
void ClearBit(int bit);  
void SetStateBit(int bit, int  
state);  
int ReadBit(int bit);
```

*Print to Console Screen**Functions:*

```
int printf(const char *format,  
...);
```

*Print to Windows File**Functions:*

```
FILE *fopen(const char*,  
const char*);  
int fprintf(FILE *f, const char  
* format, ...);  
int fclose(FILE *f);
```

*Thread Functions:*

```
void StartThread(int thread);  
void PauseThread(int thread);  
void ThreadDone();  
int ResumeThread(int  
thread);
```

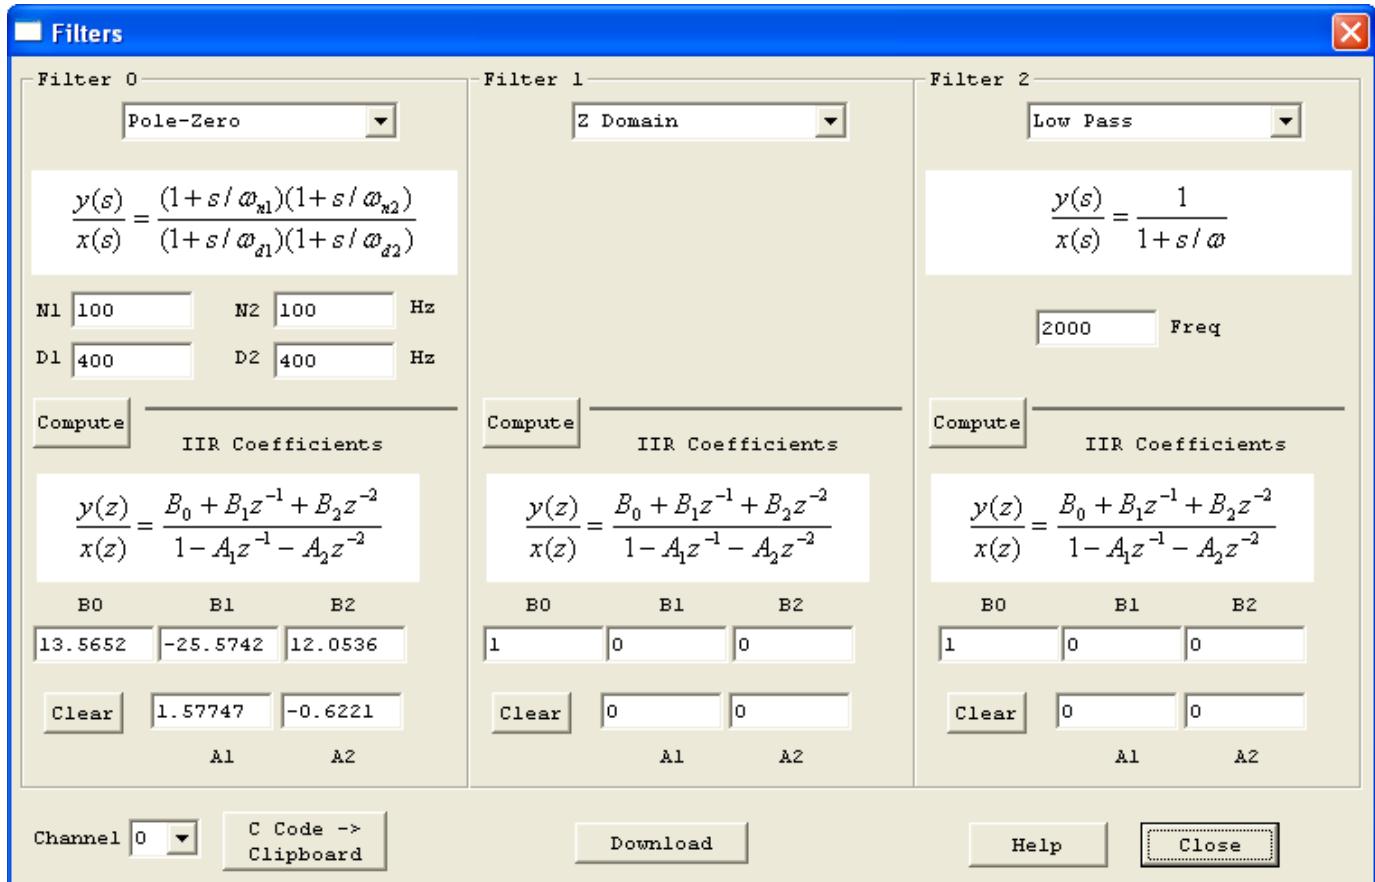

*Math Functions:*

```
double sqrt(double x);  
double exp(double x);  
double log(double x);  
double log10(double x);  
double pow(double x, double  
y);  
double sin(double x);  
double cos(double x);  
double tan(double x);  
double asin(double x);
```

```
double acos(double x);
double atan(double x);
double atan2(double y,
double x);

float sqrtf (float x);
float expf (float x);
float logf (float x);
float log10f(float x);
float powf (float x, float y);
float sinf (float x);
float cosf (float x);
float tanf (float x);
float asinf (float x);
float acosf (float x);
float atanf (float x);
float atan2f(float y, float x);
```

## IIR Filter Screen

The **IIR Filter Screen** allows setting various IIR (Infinite Impulse Response) *Filters* into the control loop. **KMotion** allows up to three - 2nd order bi-quadratic stages per axis to be connected in cascade. See the [KMotion Servo Flow Diagram](#) for the placement of the IIR Filters.

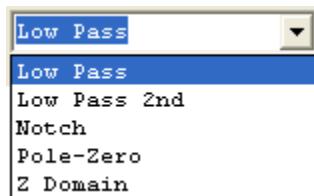

**KMotion** implements the filters using Z-domain coefficients shown on the bottom half of the screen. Because of the common confusion of the names and signs of the coefficients, the transfer function form is shown for reference.

$$\frac{y(z)}{x(z)} = \frac{B_0 + B_1 z^{-1} + B_2 z^{-2}}{1 - A_1 z^{-1} - A_2 z^{-2}}$$

Note that setting B0=1.0 and all other coefficients, B1, B2, A1, and A2, to zero causes a transfer function of unity, effectively bypassing the filter. A Clear pushbutton is available to conveniently set this mode.

B0	B1	B2
1	0	0
<input type="button" value="Clear"/>	0	0
	A1	A2

The top portion of each filter section allows various common filters to be specified in the s-domain. Supported filter types are: [1st order Low Pass](#), [2nd Order Low Pass](#), [Notch](#), and two real [poles and zeros](#) and are selected using a drop-down list box. Z-domain is a place holder used as a reminder that the z-domain coefficients were determined directly by some other means. The form of each of the filters in the s-domain is shown below.

Low Pass

$$\frac{y(s)}{x(s)} = \frac{1}{1+s/\omega}$$

Low Pass 2nd

$$\frac{y(s)}{x(s)} = \frac{1}{s^2/\omega_n^2 + Qs/\omega_L + 1}$$

Notch

$$\frac{y(s)}{x(s)} = \frac{s^2 + 2s\omega_n + \omega_n^2}{s^2 + 2\eta s\omega_n + \omega_n^2}$$

Pole-Zero

$$\frac{y(s)}{x(s)} = \frac{(1+s/\omega_{n1})(1+s/\omega_{n2})}{(1+s/\omega_{d1})(1+s/\omega_{d2})}$$

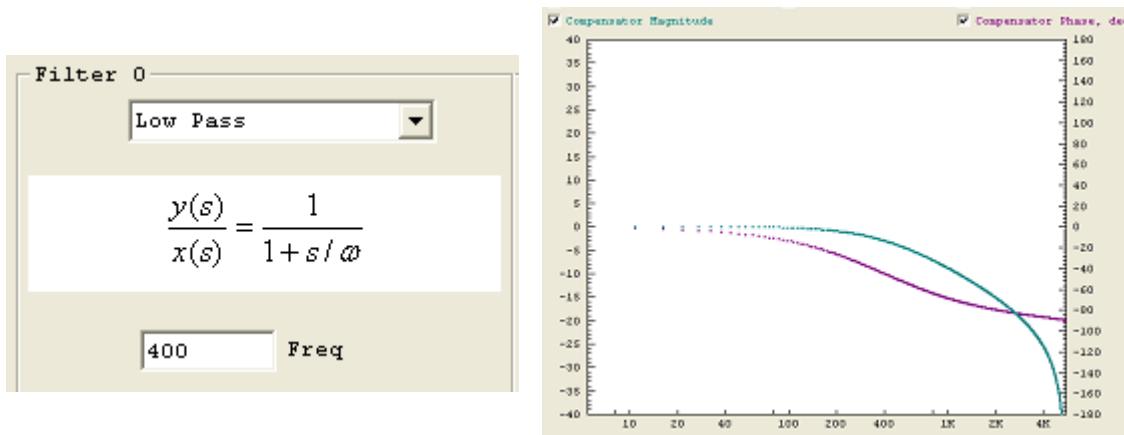

If an s-domain filter type is selected and its corresponding parameters specified, then depressing the *Compute* pushbutton will convert the s-domain transfer function to the z-domain using Tustin's approximation (with frequency pre-warping) and automatically fills in the z-domain coefficients. Note that **KMotion** always utilizes the current (most recently computed or entered) z-domain coefficients, regardless of any changes that might be made to the s-domain section.

Note that the [Bode Plot Screen](#) has the capability to graph the combined transfer function of all three IIR filters and the PID filter. This is referred to as the *Servo Compensation*. To view the transfer function of a *single* IIR filter, set the other filter and PID sections to unity (for PID set P=1, I=0, D=0 or for an IIR Filter B0=1, B1=B2=A1=A2=0).

Below are examples of each of the s-domain filter types (shown individually):

### Low Pass (1st order)

A *Low Pass* filter is commonly used in a servo system to reduce high frequency noise (or spikes) in the output. It also has the desirable effect of decreasing the gain at high frequencies. If a system's gain at high frequencies is increased sufficiently to reach 0 db it may become unstable. Unfortunately it has the effect of introducing phase lag (negative phase) which will reduce the [phase margin](#). A 1st order Low Pass filter has 45 degrees phase and attenuation of -3db at the specified cutoff frequency. The cutoff frequency should normally be specified much higher than the servo bandwidth in order to have only a small phase lag at the system's bandwidth.

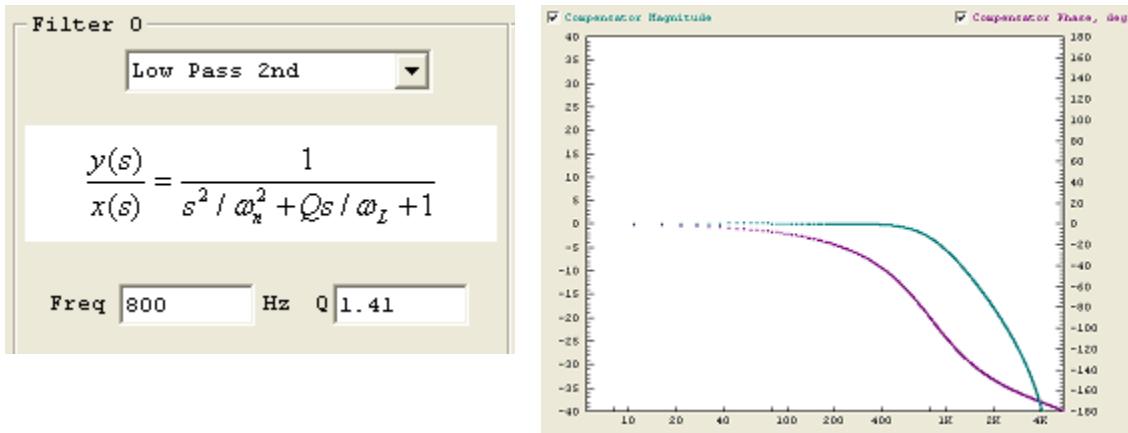

### Low Pass (2nd order)

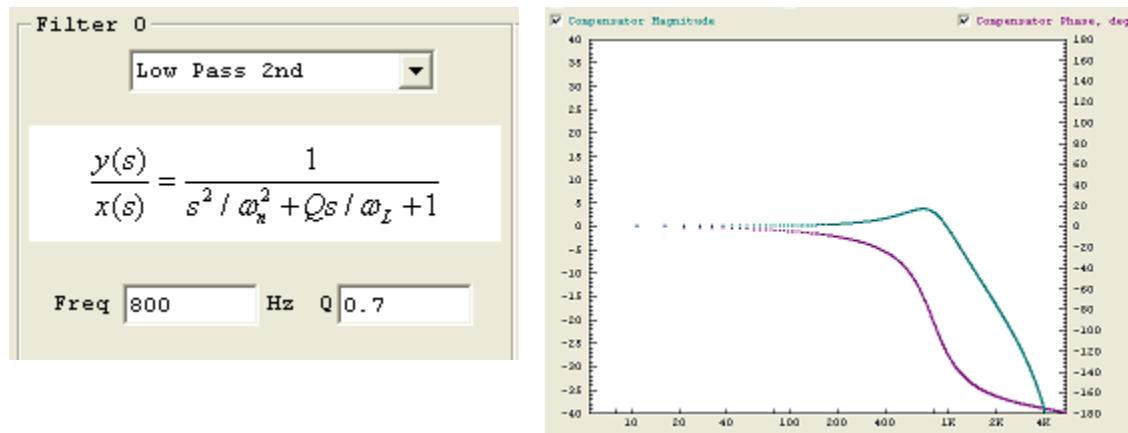

A *2nd order Low Pass* filter is commonly used in a similar manner as a [1st order low pass filter](#), except that it has higher attenuation than a 1st order low pass filter. Unfortunately it also introduces more phase lag than a 1st order low pass filter. In most cases the cutoff frequency for a 2nd order low pass filter will have to be specified at a higher frequency than a 1st order filter, in order to have similar phase lag at the system bandwidth frequency. Even so, the 2nd order low pass filter is usually preferable in that it provides slightly more high frequency attenuation and "smoothing" of the output.

A 2nd order Low Pass filter also allows a Q parameter which changes the sharpness of the filter. A smaller value of Q results in a sharper filter at the expense of some peaking (gain increases before

decreasing). A Q value of 1.41 (called a Butterworth filter), shown immediately below, is the minimal value that may be specified without peaking.

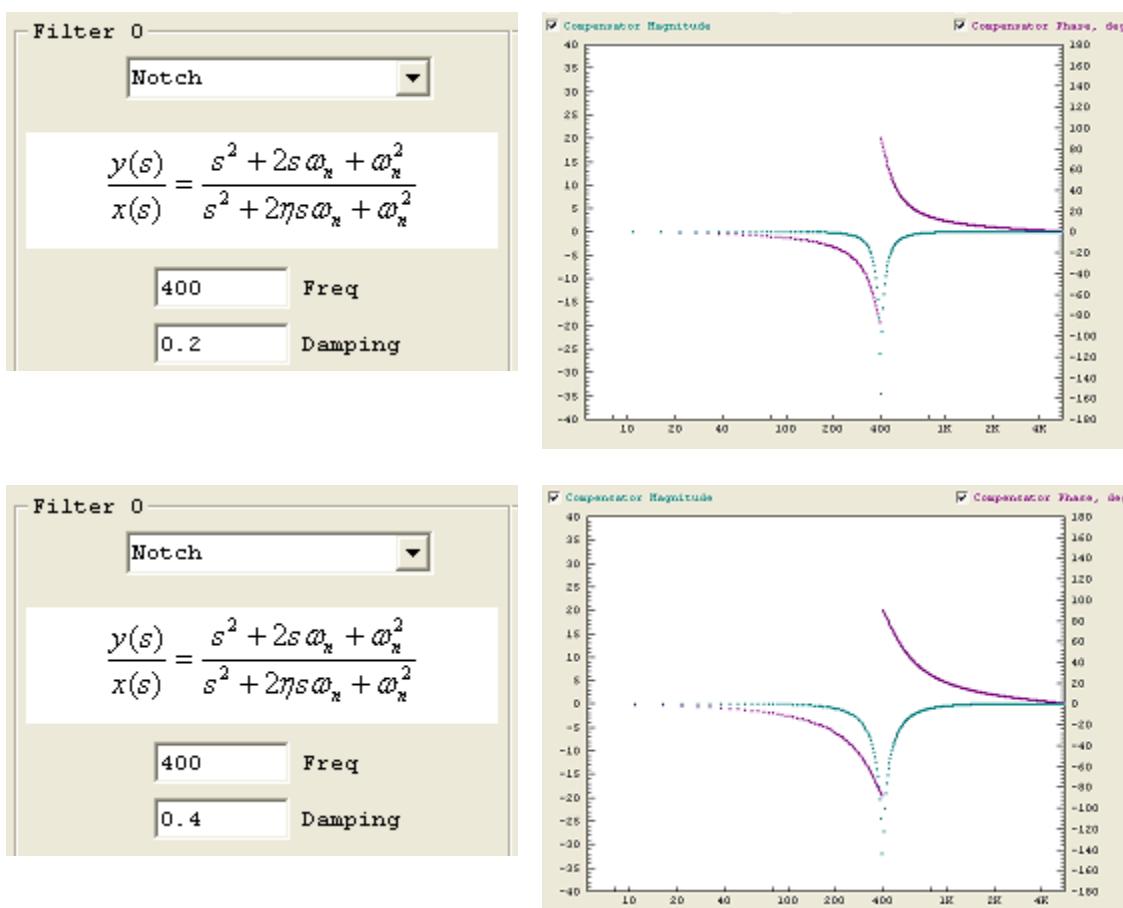

A Q value of 0.7 shows “peaking”.

## Notch

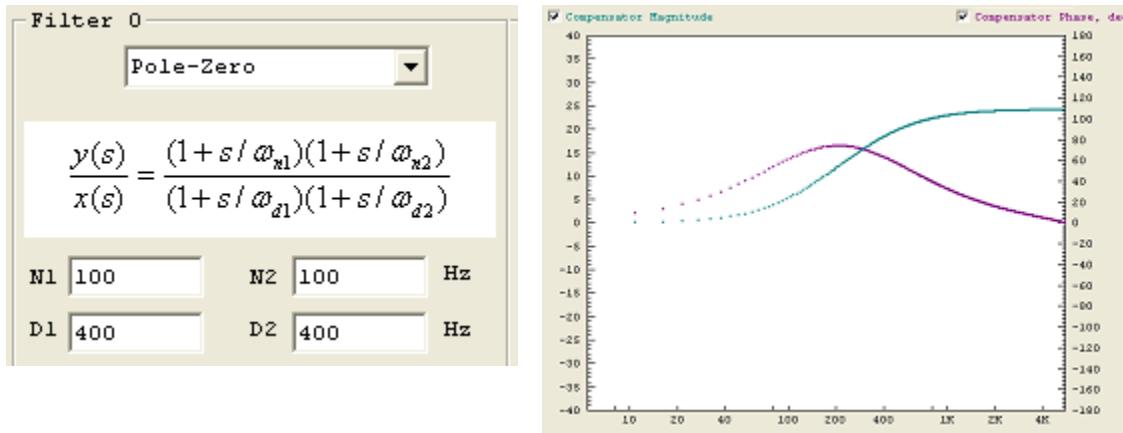

A *Notch* filter is commonly used in servo system when a sharp mechanical resonance would otherwise cause a system to become unstable. A Notch filter is able to attenuate a very localized range of frequencies. It has a damping factor,  $\eta$ , which effects sharpness or width of the notch. The disadvantage of using a notch filter is some phase lag which tends to decrease [phase margin](#). The introduced phase lag will be less the narrower the notch is (less damping), as well as the distance the notch frequency is above the system bandwidth.

Shown below are two notch filters both at 400 Hz, one with 0.2 damping and the other with 0.4 damping.

## Pole-Zero

A *Pole-Zero* filter is commonly used in a lead-lag configuration shown below to shift the phase positive at the 0 db crossover frequency of the system in order to increase [phase margin](#). The filter shown has maximum positive phase of approximately 80 degrees at 200 Hz. This is accomplished by setting the N1,N2 (zeros or numerator frequencies) 2X *lower* than 200 Hz (100 Hz), and the D1,D2 (poles or denominator frequencies) 2X *higher* than this (400 Hz). A lead-lag filter (or compensator) may often be used in place of derivative gain (in the PID stage), and has a significant advantage of lower high frequency gain. If a system's gain at high frequencies is increased sufficiently to reach 0 db it may become unstable.

### Copy C Code to Clipboard

C Code ->  
Clipboard

This pushbutton causes the current z-domain filter coefficients to be copied to the clipboard in a form that may be pasted directly into a **KMotion** C Program, see also the [C Program Screen](#).

```
ch0->iir[0].B0=232.850006;
ch0->iir[0].B1=-450.471008;
ch0->iir[0].B2=217.869995;
ch0->iir[0].A1=1.001990;
ch0->iir[0].A2=-0.250994;

ch0->iir[1].B0=1.000000;
ch0->iir[1].B1=0.000000;
ch0->iir[1].B2=0.000000;
ch0->iir[1].A1=0.000000;
ch0->iir[1].A2=0.000000;

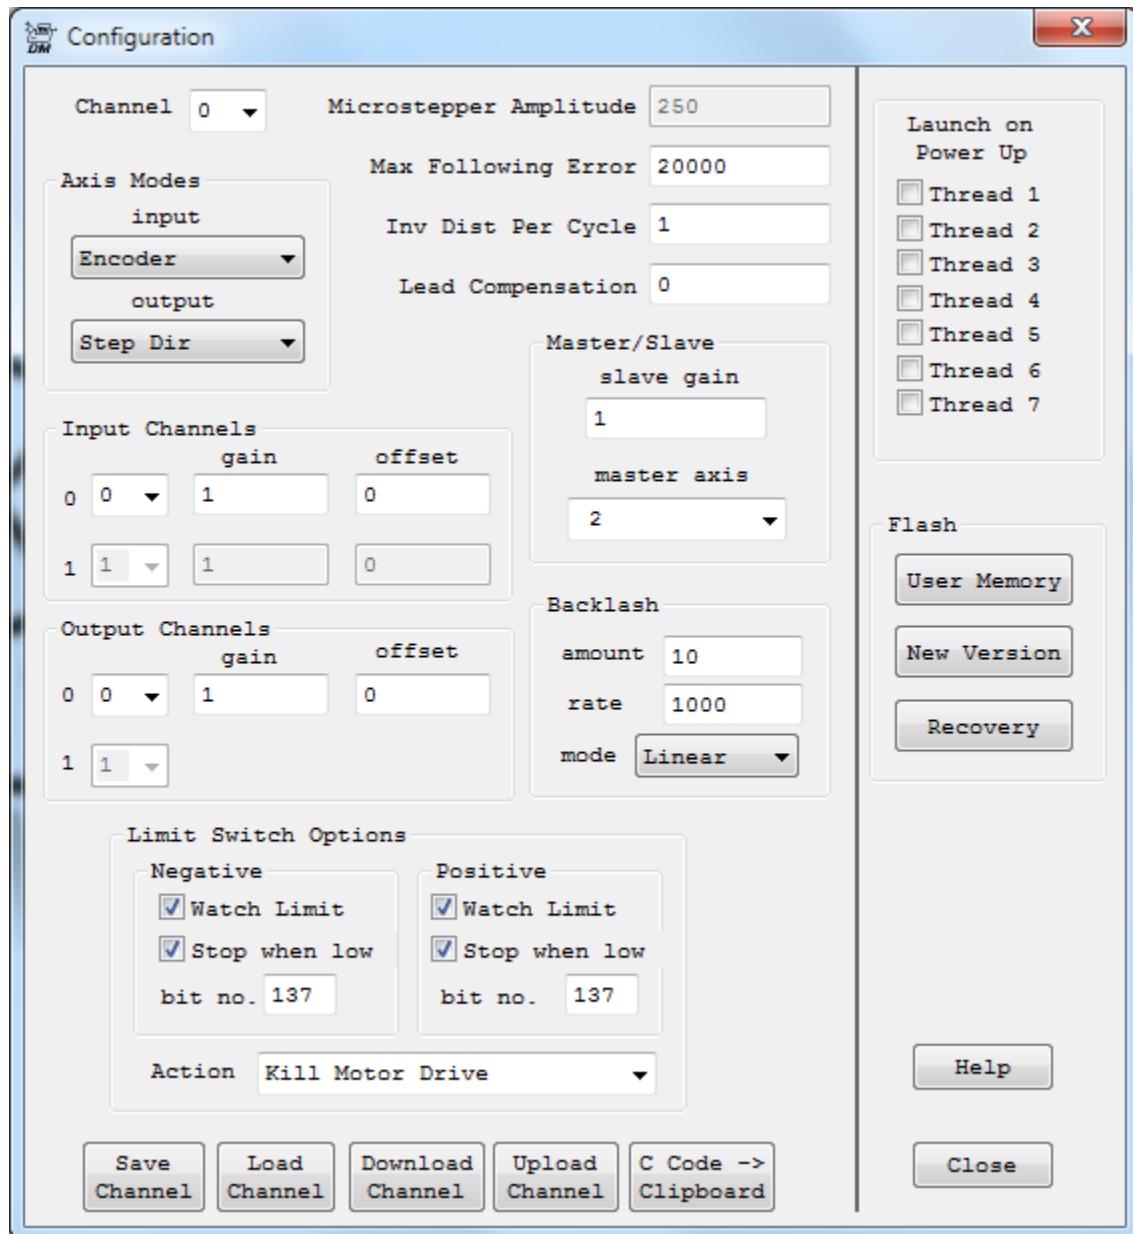

ch0->iir[2].B0=0.175291;
ch0->iir[2].B1=0.350583;
ch0->iir[2].B2=0.175291;
ch0->iir[2].A1=0.519908;
ch0->iir[2].A2=-0.221073;
```

### Download

Download

The *Download* push button downloads the filters for the selected axis (along with all axis configuration and tuning parameters) to the **KMotion**.

## Configuration and FLASH Screen

The **Configuration and FLASH Screen** displays and allows changes to **KMotion's** configuration and allows the configuration, new firmware, or user programs to be FLASH'ed to non volatile memory.

Channel **0**

Each axis channel is configured independently. To view or make changes to a configuration first select the desired axis channel using the channel drop down. Note that changing an axis on any screen switches the active channel on all other screens simultaneously.

The parameters for each axis's configuration are grouped into three classes: Definitions, Tuning, and Filters. Each class of parameters are displayed on three corresponding screens:

- Configuration Screen
- Step Response Screen
- IIR Filter Screen

The *Configuration Screen* contains *definition* parameters that should be set once and remain set unless a physical change to the hardware is made. For example, a Stepper motor might be replaced with a Brushless Motor and Encoder.

The *Step Response Screen* contains parameters that are *tuning* related and are located where the tuning response is most often adjusted and checked. For example, PID (proportional, intparameters are located there.

The *IIR Filter Screen* contains parameters related to servo *filters*.

## Utilities

Configuration settings are normally defined and tested using the KMotion Screens. After they have been determined to work properly they can be converted to C code and placed into a C program that can then be used by applications to configure KFLOP without needing to use KMotion Screens. Axis Channel Settings can also be loaded/saved to disk files. See [Flash Video](#)

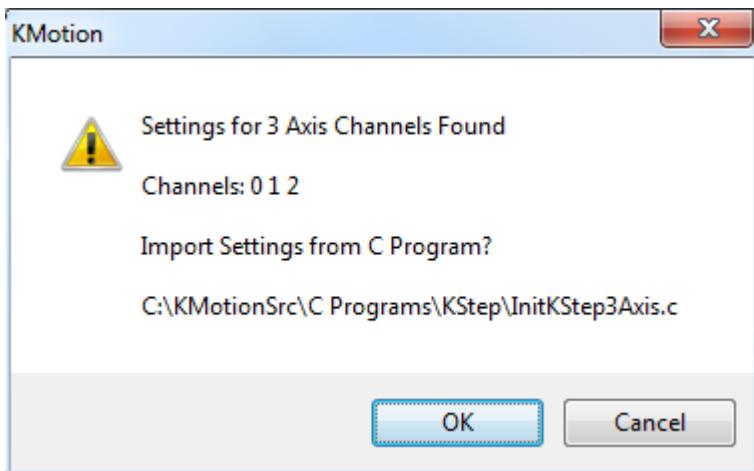

The buttons along the bottom of the Configuration Screen allow a set of axis parameters to be:

- Saved or Loaded from a disk file (\*.mot)
- Uploaded or Downloaded to a **KMotion**
- Converted to equivalent C Code for use in a [KMotion C Program](#) (note you will not see anything happen but the data will be placed in the clipboard. Paste it into a C Program to see it)

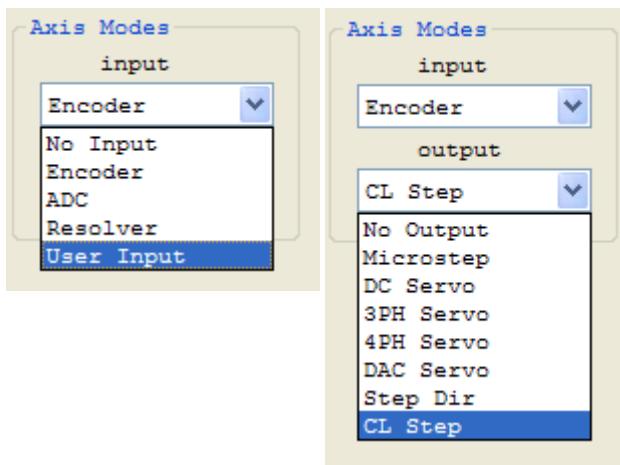

Note that these buttons operate on all parameters (for one axis) from all screens as a unit.

To completely synchronize **all** the Configuration Screens (Config/Flash, Step Response, and Filters) for **all** axes to a C Program use the **Export All to Open C Program Button**. To Import all settings from a C Program select the **Import All from Open C Program** Button. The C program must be open on the C Program Screen. In both cases the C Program will be scanned to find blocks of axis settings and will determine which axis exist in the C Program. The results of the scan will be displayed before importing or exporting the settings. The dialog box below shows an example where 3 channels were found. Select OK to proceed with the import.

## Axis Modes

Use the respective dropdown to set either the axis Input or Output Mode. The input mode defines the type of position measurement (if required) for the axis. Closed loop control always requires some type of position measurement. For open loop stepper motor control, position measurement is optional.

The output mode determines how the output command should be achieved. Either by driving the on board PWMs and Full Bridge Drivers to control a specific type of motor, by driving a DAC signal that will drive an external power amplifier, or by driving Step and Direction digital outputs.

**No Output** mode is used when no output is required or a User Program will be writing the output to some device not directly supported (ie PWM Outputs).

**Microstep** mode is used with SnapAmp to apply sine/cosine currents to a stepper motor (this does not refer to driving microstepping Step Dir Drives).

**DC Servo** mode is used with SnapAmp to drive Brushed DC Motors

**3PH Servo** mode is used with SnapAmp to drive Brushless 3 Phase Motors.

**4PH Servo** mode is used with SnapAmp to drive Brushless 4 Phase Motors (ie Steppers as servos)

**DAC Servo** mode is used with Kanalog DACs to drive Analog Amplifiers.

**Step Dir** mode is used with open loop Step/Direction Drives (ie KStep or other external Drives). Note KFLOP outputs "steps" to external drives and whether the drive interprets the "steps" as microsteps or full steps or servo steps are dependent on the Drive.

**CL Step** mode is used with Step/Direction Drives in a closed loop manner with feedback.

For External Step and Direction Outputs see [Step and Direction Output Mode](#) and [Closed Loop Step/Dir Output Mode](#).

## Input Channels

The Input Channels section specifies which channels for the selected input device will be used. Some Input Modes require two devices to be specified and some Input Modes only require one device. If the selected Input Mode only requires one device then the second Input Channel (Input Chan 1) is not used and may be set to any number. This may be the channel of an Encoder input or an ADC input depending on the

selected input mode. Resolvers requires two ADC input channels (for sine and cosine), for all other modes the second channel number is not used.

The gain and offset parameters are applied to the respective input device. The gain is applied before the offset, i.e.  $x' = ax + b$ , where  $a$  is the gain and  $b$  is the offset.

*Incremental encoders* only utilize the gain parameter which may be used to scale or reverse (using a negative gain) the measurement.

A *Resolver* is a device that generates analog sine and cosine signals as its shaft angle changes. Either one or multiple sine and cosine waves may be produced per revolution of a resolver. An encoder that generates analog sine and cosine signals may also be connected to a **KFLOP** as though it was a resolver. Resolver inputs may utilize both gains and offsets and be adjusted such that the sine and cosine ADC measurements are symmetrical about zero and have the same amplitude. Gain and offset errors may be introduced by either the ADC input circuitry and/or the Resolver itself. If one were to plot the sine vs. cosine signals as a resolver's position changes, the result should be circle. **KFLOP** computes the arctangent of the point on the circle (also keeping track of the number of rotations) to obtain the current position. An offset or elliptical "circle" will result in a distorted position measurement throughout the cycle. Therefore note that adjusting the gains and offsets will result in changing the linearity of the position measurement, not the scale of the position measurement itself. The scale of a resolver input will always be  $2\pi$  radians per cycle.

An ADC input uses a single absolute ADC channel input to obtain the position measurement. Gain0 and Offset0 may be used to modify the ADC counts from -2048 .. +2047 to and desired range.

## Output Channels

The Output Channels section specifies which channels for the selected output device will be used. Some Output Modes require two devices to be specified and some Output Modes only require one device. For Output modes that only require one output device the second device will be disabled. If the selected Output Mode only requires one device then the second Output Channel (Output Chan 1) is not used and may be set to any number. The specified output device may be the channel of a [PWM](#) connected to an on-board power amplifier, a Step/Direction Generator, or a DAC that is used to drive an external power amplifier.

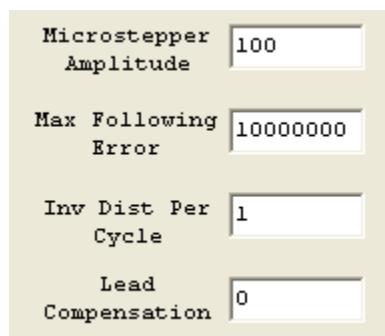

Stepper mode and 4 phase brushless mode require two channels of PWM to be specified.  
DC Servo motor (Brush motor type) only require one PWM channel.

3 Phase brushless motors require a consecutive pair of PWM channels. In 3 Phase output mode, only the Output Channel 0 value is used and must be set to an even PWM number.

For Step and Direction output mode and CL Step (Closed Loop Step/Dir), the output channel 0 is used to specify which Step/Direction Generator will be used and drive mode (active high/low or open collector) will be used. Each Step/Direction Generator has assigned I/O Pins. See [Step and Direction Output Mode](#).

Some output devices support the application of a gain and offset. See also the related Console Commands [OutputGain](#) and [OutputOffset](#).

## Microstepper Amplitude, Max Following Error, Inv Dist Per Cycle, Lead Compensation

*Microstepper Amplitude* is only applicable to configurations with output mode of Microstepper. This parameter sets the amplitude (of the sine wave) in PWM counts (0 .. 255) that will be output to the sine and cosine PWM channels while moving slowly or at rest. Note that at higher speeds **KFLOP** has the ability to increase the amplitude to compensate for motor inductance effects and *may* actually be higher. See *Lead Compensation* in this same section.

*Max Following Error* is applicable to all closed loop servo output modes (DC Servo, 3 Phase Brushless, 4 Phase brushless, and DAC Servo). Whenever the commanded destination and the measured position differ by greater than this value, the axis will be disabled (if this axis is a member of the defined coordinate system, then any coordinated motion will also stop). To disable following errors set this parameter to a large value.

*Inv Dist Per Cycle* applies to Stepper, 3 Phase, and 4 Phase motors. For a stepper motor, the *distance per cycle* defines the distance that the commanded destination should change by for a motor coil to be driven through a complete sinusoidal cycle. Parameter should be entered as the inverse (reciprocal) of the distance per cycle. Stepper motors are most often characterized by shaft angle change per "Full Step". A motor coil is driven through a complete cycle every four - "Full Steps". See the following examples:

**Example #1:** A mechanism moves 0.001" for each full step of a step motor It is desired for commanded distance to be in inches.

Result: One Cycle = 4 full steps = 0.004", Thus InvDistPerCycle =  $1.0/0.004 = 250.0$  (cycles/inch). Commanding a move of 1.00 will generate 250 sine waves, or the equivalent of 1000 full steps, or one inch of movement.

**Example #2:** InvDistPerCycle is left at the default value of 1.0

Result: Move units are in cycles. Commanding a move of 50 will generate 50 sine waves, or the equivalent of 200 full steps, or one revolution of a 200 Step or 1.8 degree motor.

For 3 Phase or 4 Phase motors, *Inv Dist Per Cycle* represents the inverse of the distance for one complete commutation cycle. See the example below.

**Example #3:** A 3 phase motor/encoder has a 4096 count per revolution encoder which is used for position feedback and for motor commutation. InputGain0 is set to 1.0 so position measurement remains as encoder counts. The motor design is such that the commutation goes through 3 complete cycles each motor revolution.

Result: One Cycle = 4096 counts/3.0 Thus InvDistPerCycle =  $3.0/4096 = 0.000732421875$ .

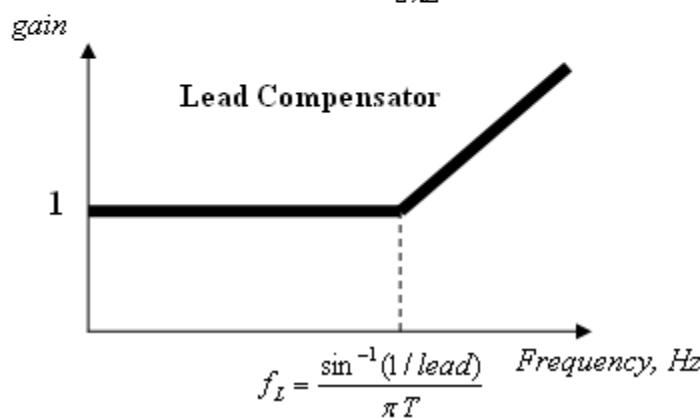

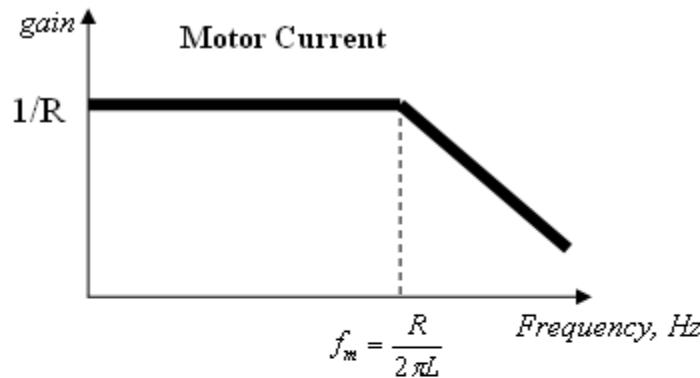

Note that it is important to use a high degree of precision to avoid commutation errors after moving to very large positions (or at constant velocity for a long period of time). **KFLOP** maintains *Inv Dist Per Cycle* (as well as position) as a double precision (64 bit) floating point number for this reason (*more than 70 years* at 1 MHz would be required to have 1 count of error)

*Lead Compensation* may be used to compensate for motor inductance. When a voltage is applied to a coil at a low frequencies, the current flow is dictated by the coil's resistance and is constant. As

$$f_m = \frac{R}{2\pi L}$$

the frequency increases at some point, where  $f_m = \frac{1}{2\pi L}$ , the inductance,  $L$ , begins to dominate and the current drops (see plot below). **KFLOP's** Lead Compensator has the opposite effect, it has a constant gain of 1 and at some point increases with frequency. The Lead Compensation parameter sets (indirectly) the frequency where this occurs. If the frequency is set to match the frequency of the motor, the effects will cancel, and the motor current (and torque) will remain constant to a much higher frequency.

This assumes that the nominal drive voltage is lower than the available supply voltage. For example, a 5V stepper motor might be driven with a 15V supply to allow head room for the applied voltage to be increased at high frequencies (speeds).

$$lead = \frac{1}{2 \sin(\pi T f_L)}$$

The simple formula that implements the Lead Compensation is:

$$v' = v + \Delta v L$$

where  $v$  is the voltage before the compensation,  $v'$  is the voltage after the compensation,  $\Delta v$  is the change in output voltage from the last servo sample, and  $L$  is the Lead Compensation value.

The following formula will compute the "knee" frequency for a particular *lead* and servo sample rate (normally  $T=90$  us).

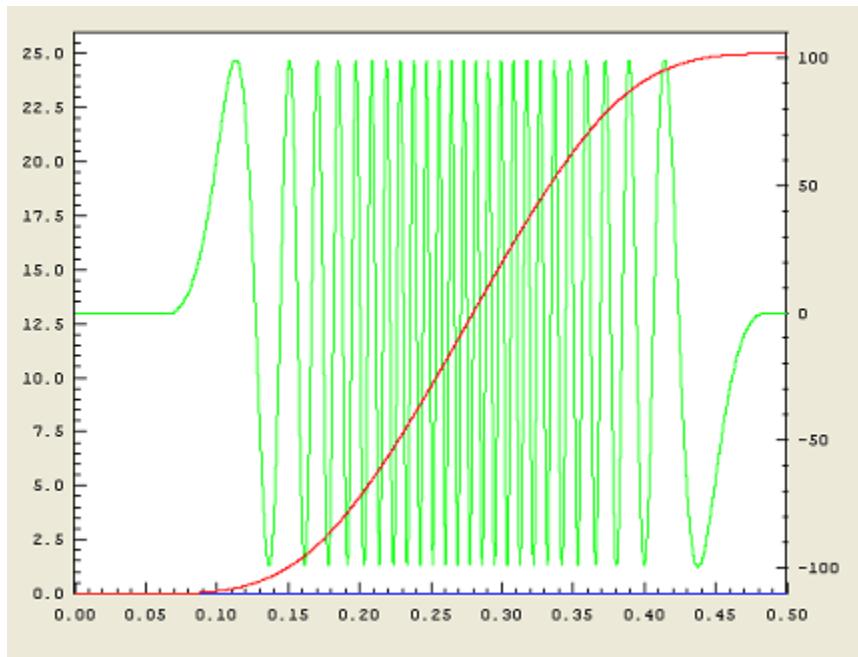

$$f_L = \frac{\sin^{-1}(1/lead)}{\pi T}$$

or the inverse of this formula will provide the lead value to position the knee at a particular frequency.

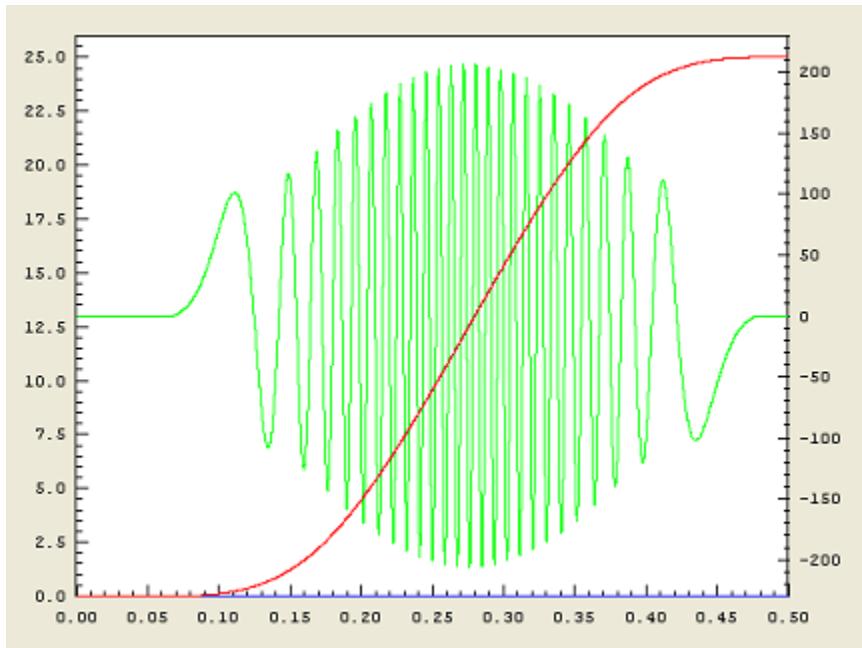

The Following table generated from the above formula may also be used. For most motors the Lead Compensation values will be within the range of 5 - 20.

Freq, Hz	Lead
50	35.37
60	29.47
70	25.26
80	22.11
90	19.65
100	17.69
120	14.74
140	12.63
160	11.06
180	9.83
200	8.85

220	8.04
240	7.37
260	6.81
280	6.32
300	5.90
350	5.06
400	4.43
450	3.94
500	3.55
550	3.23
600	2.96
650	2.74
700	2.54
750	2.38
800	2.23
850	2.10
900	1.99
950	1.88
1000	1.79

This plot above displays a simple 0.5 second motion with no Lead Compensation for a Microstepper Motor. Position axis shown on the primary (left axis) for the red plot has units of cycles. PWM output shown on the secondary (right axis) for the green plot has units of PWM counts. Move parameters are: Vel=200 cycles/sec, Accel=200 cycles/sec<sup>2</sup>, Jerk=10000 cycles/sec<sup>3</sup>. Note that regardless of velocity PWM amplitude is constant.

This plot displays the same 0.5 second motion with Lead Compensation = 27.0. All other parameters same as above. Note how PWM amplitude increases with velocity

If motor parameters are unknown, a trial and error approach may be used to find the best lead compensation value. The following procedure may be used:

1. Set Lead Compensation to zero
2. Increase motor speed until a drop in torque is first detected
3. Increase Lead Compensation until normal torque is restored

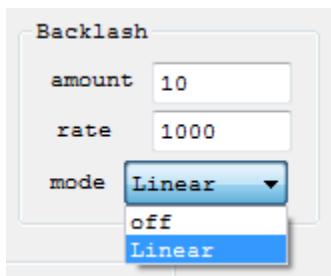

Setting the Lead Compensation too high should be avoided, as it may cause over current in the motor at medium speeds or voltage distortion due to saturation (clipping).

## Master/Slave Settings

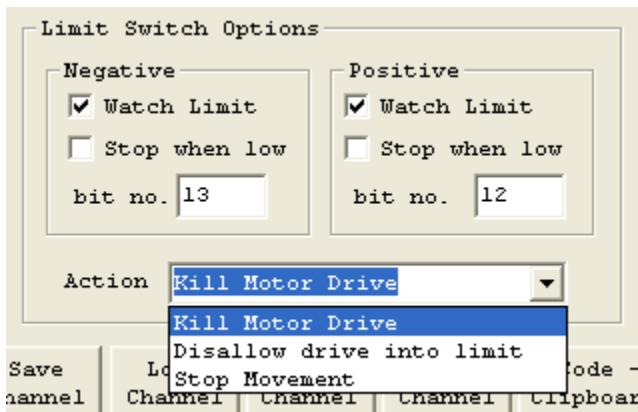

Configures the axis to be slaved to another axis. If slaved when the master axis moves, this axis will be commanded to move by an amount as scaled by the slave gain. If the Slave Gain is negative the slaved axis will move in the opposite direction as the Master. See also Console commands [SlaveGain](#) and [MasterAxis](#). Setting the Master axis as -1 will disable slaving for this axis.

## Backlash Settings

Configures the Backlash Compensation for the axis. To compensate for backlash in an axis, an offset in the commanded position may be applied when moving in the positive direction, and not applied when moving in the negative direction. The amount and rate at which the offset is applied is specified here. See also [BacklashMode](#), [BacklashAmount](#) and [BacklashRate](#) Console commands.

## Limit Switch Options

**KFLOP** has the ability to monitor limit switch inputs for each axis and stop motion when a physical limit switch is detected. The limit switch options allow this feature to be enabled or disabled for each limit (positive or negative), what specific bit to be monitored for each limit, what polarity of the bit indicates contact with the limit, and what action to perform when a limit is detected.

Select *Watch Limit* to enable limit switch monitoring.

Select *Stop when low* to select negative true logic for the limit (motion will be stopped when a low level is detected).

Specify a *bit no.* for which bit is to be monitored for the limit condition. See the [Digital IO Screen](#) for current I/O bit status and a recommended bit assignment for limit switches (bits 12 through 19). If in a particular application it isn't critical to determine which Limit Switch (either positive or negative, or even which axis) the number of digital I/O bits consumed by limit switches may be reduced by "wire ORing" (connecting in parallel) multiple switches together. In this case, the same bit number may be specified more than one place.

The Action drop down specifies what action should be performed when a limit is encountered.

*Kill Motor Drive* - will completely disable the axis whenever the limit condition is present. Note that it will not be possible to re-enable the axis (and move out of the limit) while the limit condition is still present and this mode remains to be selected.

*Disallow drive into limit* - will disable the axis whenever the limit condition is present and a motion is made into the direction of the limit. This mode will allow the axis to be re-enabled while inside the limit and will allow a move away from the limit.

**Stop Movement** - this action will keep the axis enabled, but will FeedHold the Coordinate System. This will cause commanded positions to decelerate to a stop in a controlled manner. Independent motions will decelerate to a stop in the same manner as a Jog to zero speed would cause. Coordinated Motion will decelerate all axes to a stop along the motion path.

The FeedHold mode will remain and prevent any further motion until cleared. In KMotion.exe the

button will flash and can be pushed to clear the Feedhold. In KMotionCNC Feedhold can be

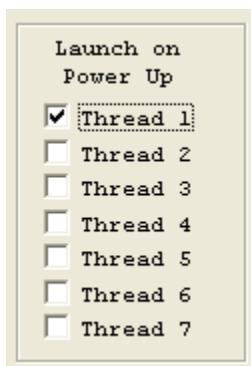

cleared by pushing . If further motion is attempted into the Soft Limit another Feedhold will occur. However, if no motion, or motion out of the Limit, Feedhold will remain clear and the motion will be allowed.

## Soft Limits

Soft Limits will always prevent motion in the same manner as a Hardware Limit with the Stop Movement Action Selected. This occurs regardless of the Action Type Selected for the Hardware Limit Switches. To disable Soft Limits set them to a huge range which could never occur. Soft Limits prevent motion within KFLOP when Jogging, moving and so forth. They also are uploaded by Applications such as KMotionCNC and used to prevent motion during Trajectory Planning.

## Launch on Power Up

The launch on power up configuration specifies which User Programs are to be automatically launched on power up for stand alone operation of **KFLOP**. See the [C Program Screen](#) for information on how to Edit, Compile, and Download a C program into **KFLOP** for execution into one (or more) of the 7 Thread program spaces within **KFLOP**.

To configure a program execute on power up, perform the following steps:

1. *Compile and Download a C Program to a particular Thread Space.*
2. *Select Launch on Power Up for the same Thread.*
3. *Flash the User Memory (see following section).*
4. *Disconnect the Host USB cable*
5. *Cycle Power on the **KFLOP***

## FLASH

The entire user memory space may be Flashed into nonvolatile memory by depressing the *Flash - User Memory* button. This saves all of the axis configurations, all user program thread spaces, and the user persistent data section. On all subsequent power up resets, **KFLOP** will revert to that saved configuration. (note that it is preferred to have the host, or a user program, configure the board before each use rather than relying on the exact state of a KMotion set to a particular state at some point in the past).

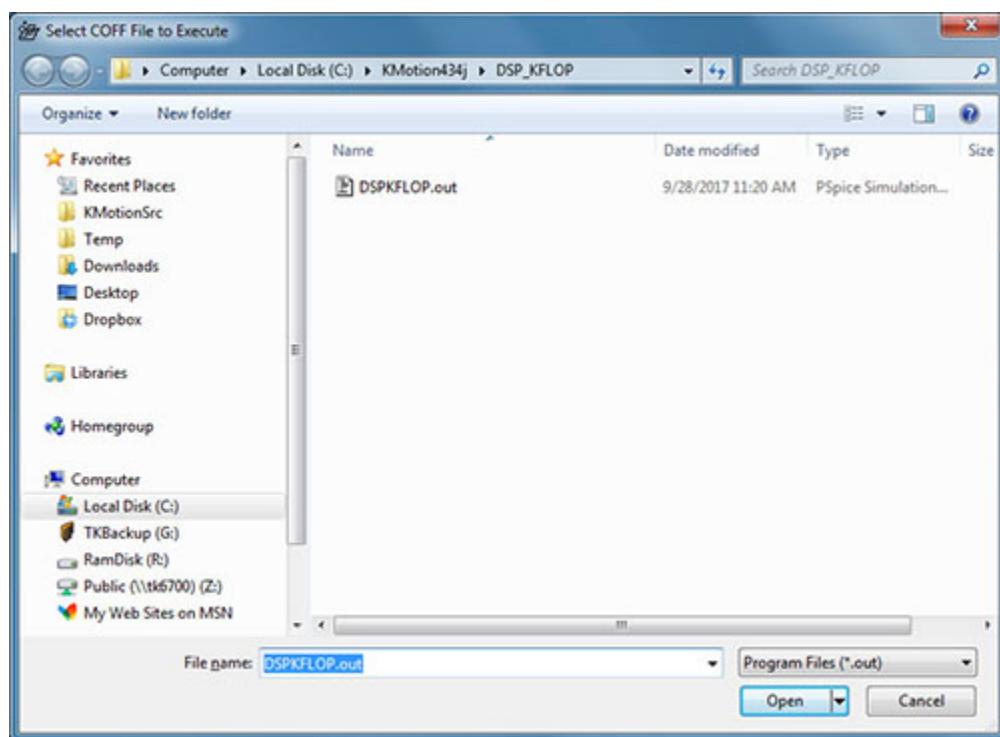

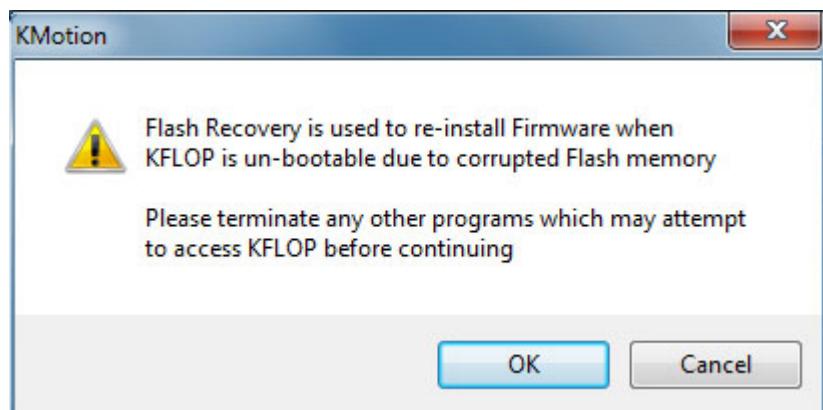

To upgrade the system firmware in a **KFLOP** use the *Flash - New Version* button. The user will be prompted to select a **DSPKFLOP.out** COFF file from within the **KMotion** Install Directory to download and Flash. Note that all user programs and data will be deleted from **KFLOP** when loading a new version.

After the firmware has been flashed it is necessary to re-boot the **KFLOP** in order for the new firmware to become active.

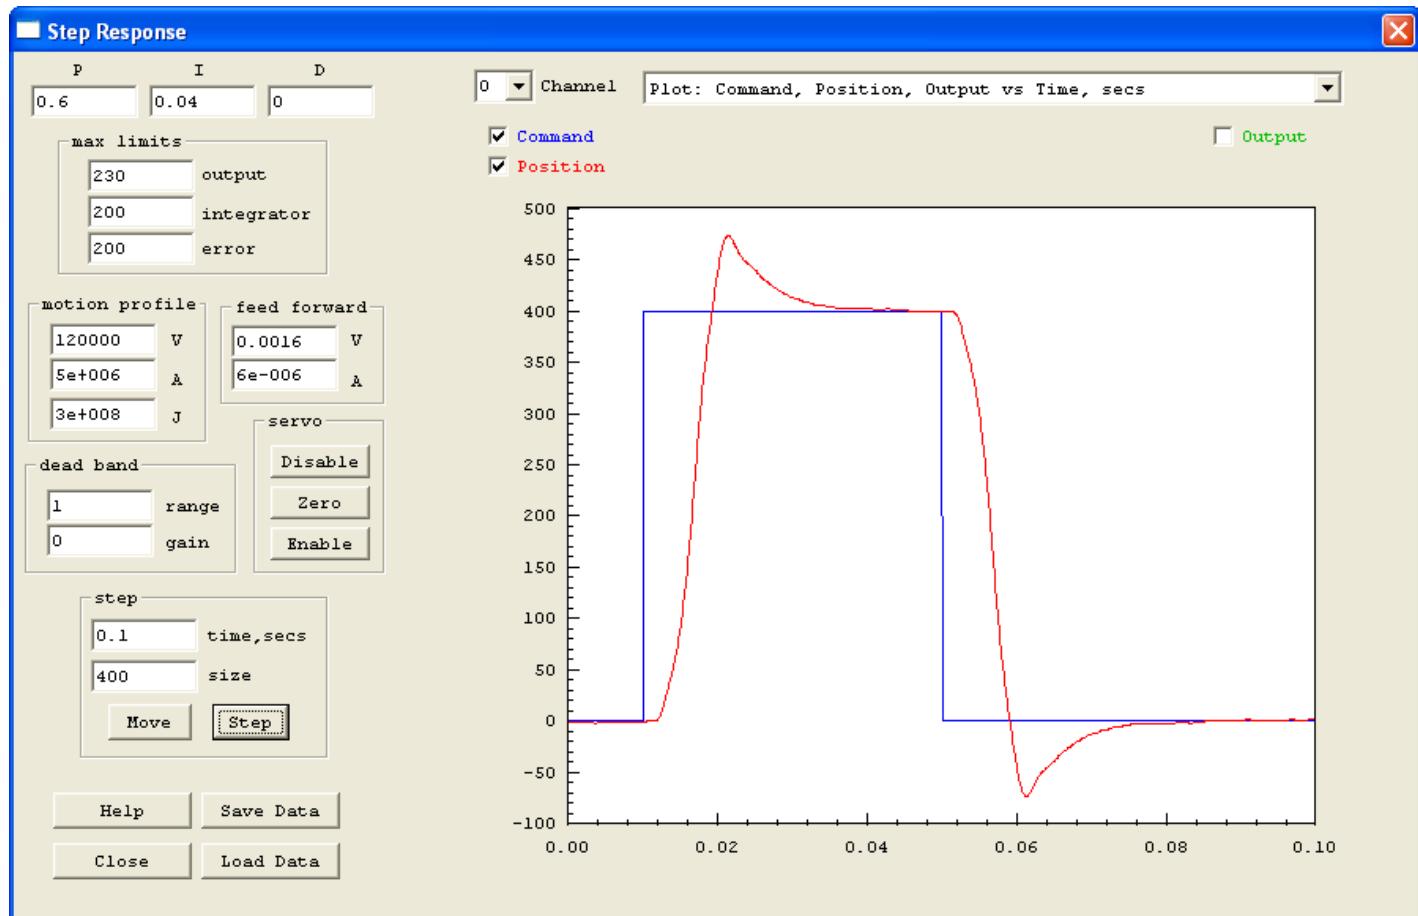

It is important that the <Install Directory>\DSP\_KFLOP\DSPKFLOP.out file match the firmware that is flashed into **KFLOP**. User C programs are *Linked* using this file to make calls and to access data located within the **KFLOP** firmware. Whenever a user program is compiled and linked using this file, the timestamp of this file is compared against the timestamp of the executing firmware (if a **KFLOP** is currently connected). If the timestamps differ, the following message will be displayed, and it is not recommended to continue. The "Version" Console Script Command may also be used to check the firmware version.

In all cases while flashing firmware or user programs the process should not be interrupted or a corrupted flash image may result which renders the board un-bootable. However if this occurs the *Flash Recovery* mode may be used to recover from the situation. To perform the recovery, press the *Flash Recovery* button and follow the dialog prompts to:

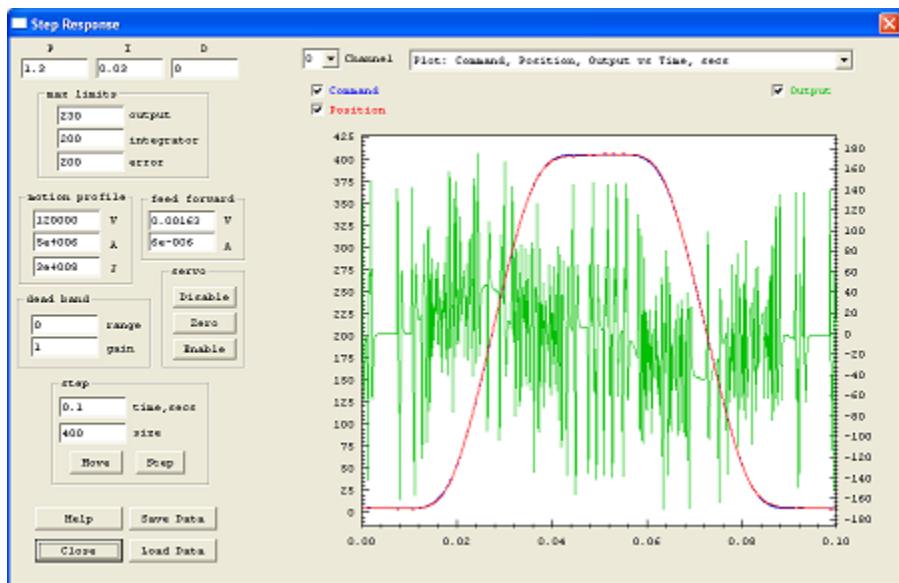

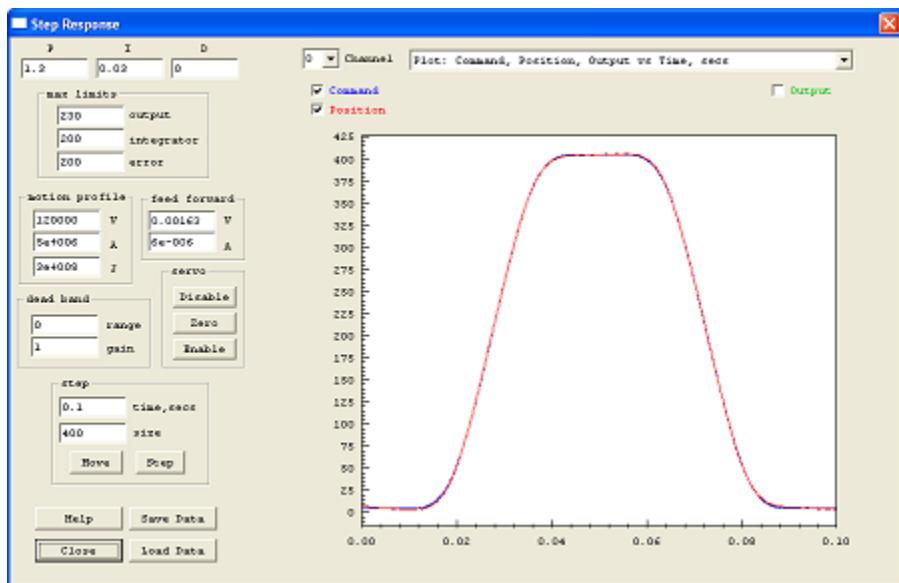

1. Turn off **KFLOP**
2. Run **KMotion.exe**, Config/Flash Screen, select "Recovery"
3. Click OK (see below)
4. Select the **DSPKFLOP.out** file to boot (see below)
5. Click OK
6. When prompted, turn on **KFLOP**
7. After **KFLOP** boots, Flash the New Version

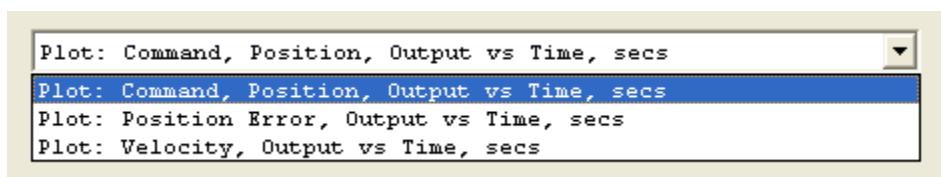

## Step Response Screen

The **Step Response Screen** allows changes to system tuning parameters and allows measurement and graphs of the system's time response for either a Move Profile or a Step Function. The graph shown above is of an applied step function of 400 counts. The graphs shown below are of a profiled move (and back) of 400 counts. The first has the Output drive hidden and the second has the Output drive displayed. Click on the graphs for a larger view. Note that the Output drive signal contains large spikes. This is the result of quantization error in the measured position. Quantization error in the measured position makes it appear to the system as if there was no motion, and then suddenly as if there was a relatively quick motion of one count in a single servo sample cycle. This is a [non-linear effect](#). In some cases these "spikes" may exceed the output range causing saturation a still further non-linear effect. A low pass filter may be used to "smooth" the output, see the [IIR Filter Screen](#), but has limits. Attempting too much "smoothing" by setting a lower frequency will eventually have an effect on the performance of the system, reducing the [phase margin](#). Normally, the cutoff frequency of the low pass filter should be significantly larger than the system bandwidth.

There are three basic time domain plot types that may be selected from the drop down list, which are shown below.

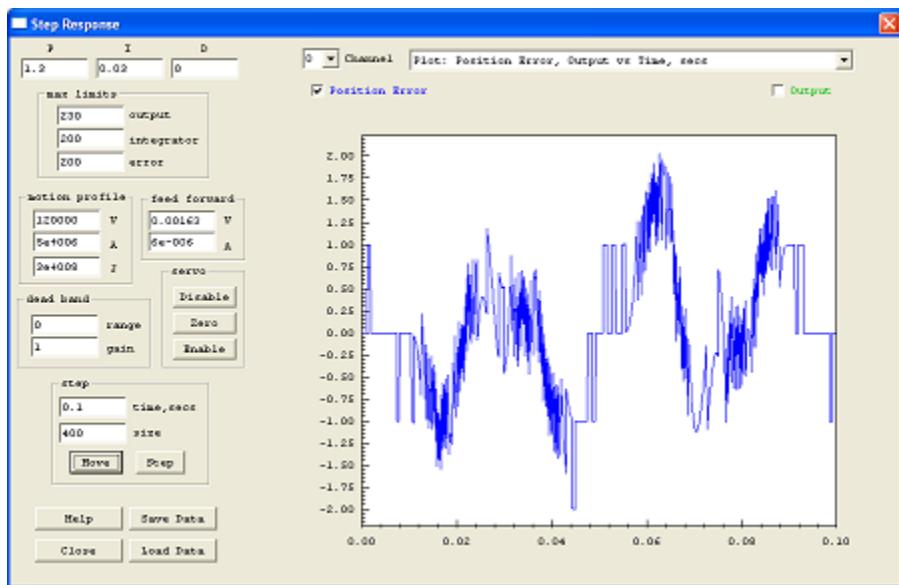

They consist of either:

1. Commanded Position, Measured Position, and Motor Output
2. Position Error and Motor Output
3. Commanded Velocity, Measured Velocity, and Motor Output

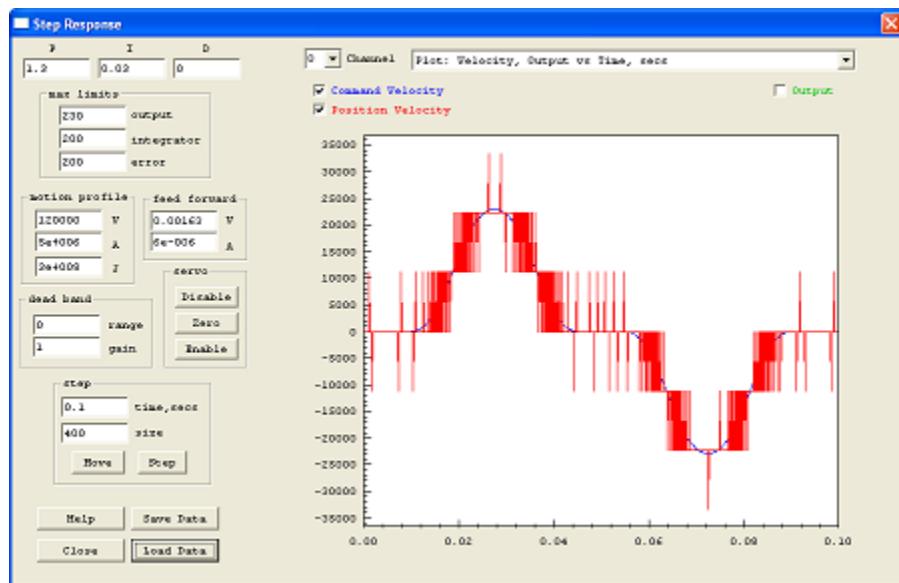

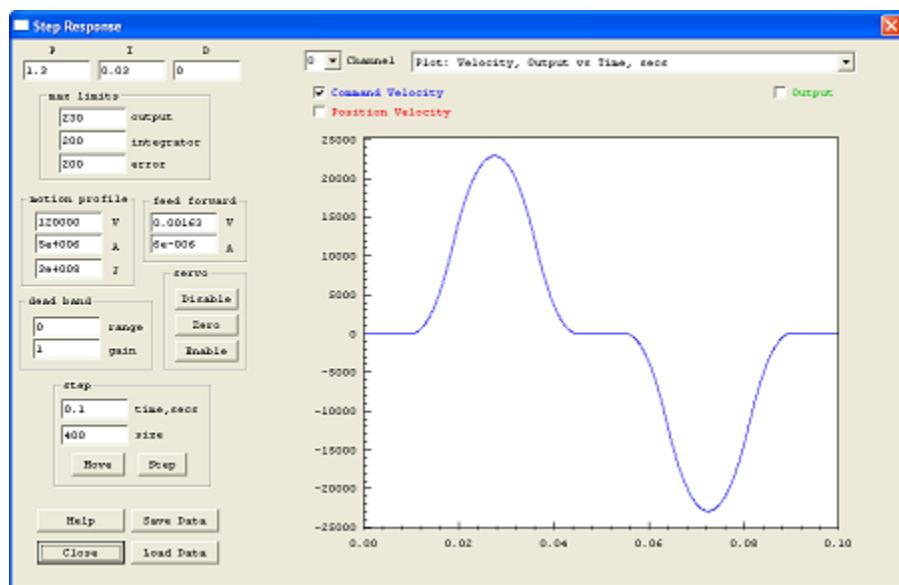

For all three plot types the Motor Output is always displayed as a secondary Y axis on the right side of the graph. The other plotted values are on the primary left Y axis. The X axis is always time in seconds. After a particular plot type has been selected, each individual plot variable may be displayed or hidden by selecting the checkbox with the corresponding name (and color) of the variable.

Any portion of the graph may be zoomed by left-click dragging across the graph. Simply select the area of interest. Right clicking on the graph will bring up a context menu that allows zooming out completely or to the previous zoom level.

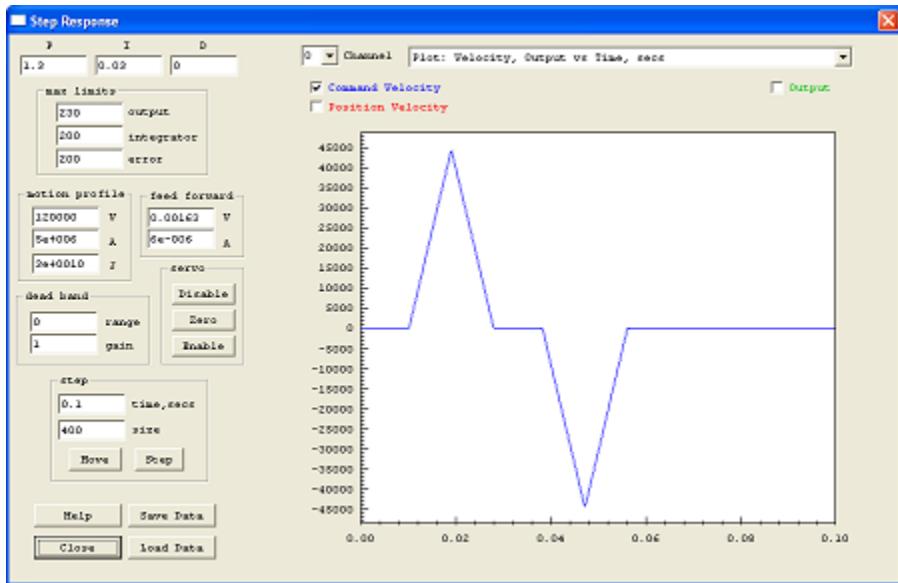

Below is an example of a graph of *Position Error* (for the same 400 count move shown above). Position Error is defined as Measured Position - Commanded Position. The same data as that is plotted in the Command/Position plots is used, however instead of plotting both values, the difference is plotted. Note that because the Measured Position is quantized to integer encoder counts, the quantization effect is also observed in the Position Error.

The third type of plot displays the Velocity of the Commanded and/or Measured Position. Velocity units are *Position Units* per second. When a Move is commanded, a motion profile is computed which achieves the motion in the shortest time without exceeding the maximum allowed velocity, acceleration, or jerk. Because the Command is a theoretical profile computed using floating point arithmetic, it is very smooth. The blue graph immediately below shows such a plot. In a velocity graph, *slope* in the graph represents acceleration. In this case a relatively low value specified for maximum jerk causes the changes in slope to be gradual. The second plot below is the same data but with the *Measured* velocity displayed along with the Commanded velocity. Because of encoder resolution limitations, measured velocity calculated using a simple position difference per sample period tends to be highly quantized as shown. In this example even at our peak velocity at ~ 23,000 position counts per second this results in a maximum of only 3 position counts per servo sample period.

The velocity graph below, shows the effect of setting the maximum allowed jerk to a very large value (100X higher than the graph above). Note how the slope of the velocity changes abruptly which represents a high rate of change of acceleration (jerk).

## Tuning Parameters – PID

P	I	D
1.3	0.03	0

The PID (proportional, integral, and derivative) gains set the amount of feedback of the error itself (proportional), the integration of the error (integral), and the derivative of the position (derivative) that is applied to the output. Also see the [KMotion Servo Flow Diagram](#).

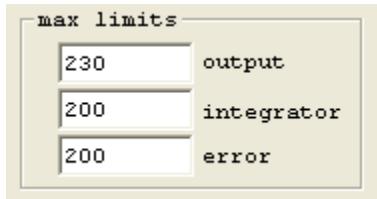

The units of the proportional gain are in Output Units/Position Units. For example if the Position Units are in encoder counts, and the Output Units are in [PWM counts](#), then a gain of 10.0 would apply an output drive of 10 PWM for an error of 1 encoder count.

The units of the integral gain are in Output Units/Position Units per *Servo Sample Time*. **KMotion's** *Servo Sample Time* is fixed at 90 $\mu$ s. An integrator basically sums the position error every servo sample. For example, with an integral gain of 10, and an error of 1 encoder count for 5 servo samples, an output drive of 50 PWM counts would be applied. Integrator gain is normally used to achieve high accuracy. This is because even a very small error will eventually integrate to a large enough value for there to be an corrective action. In fact, having any integrator gain at all guarantees a steady state error (average error) of zero. This effect also guarantees that there will always be some overshoot in response to a step function, otherwise the average error could not be equal to zero.

The units of the derivative gain are in Output Units/Position Units x *Servo Sample Time*. The derivative term is simply the change in position from one servo sample to the next. For example, with a derivative gain of 10, and a position change of 1 encoder count from the previous servo sample, an output drive of -10 PWM counts would be applied. The negative sign shows that the output is applied in a manner to oppose motion. Derivative gain has the effect of applying damping,

which is a force proportional and opposite to the current velocity. Although derivative gain is often used successfully in a control system, consider using a lead/lag filter which performs in a similar manner, but doesn't have the undesirable feature of increasing gain at high frequencies.

## Tuning Parameters - max limits

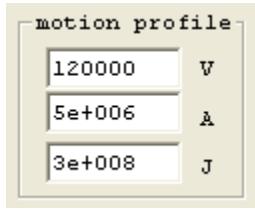

**KMotion's max limits** allow several points in the [Servo Flow Diagram](#) to be clamped, or limited to a specified range. The limits in the flow diagram are shown as a clamp symbol  . This capability is often useful in controlling how the system responds to extreme situations.

Maximum *output* limit is used to limit the maximum applied value, in counts, to the output drive. The output drive may be either one of the on-board [PWM outputs](#) or a [DAC value](#) that drives an external amplifier.

Maximum *integrator* limit is used to restrict the maximum value of the integrator. This effect is often used to avoid an effect referred to as integrator "wind up". Without any integrator limit, consider the case where somehow a substantial error is maintained for a significant period of time. For example turning a motor shaft by hand for several seconds. During this time the integrator would ramp up to an extremely large value. When the motor shaft was released, it would accelerate at maximum and overshoot the target by a huge amount until the integrator could ramp back down to a reasonable value. This often results in a servo slamming into a limit. The maximum integrator limit prevents this from occurring. Often the main purpose for using an integrator is to overcome static friction in order to reduce the final error to zero. This usually requires only a small fraction of total output range. In almost all cases it is of no value to allow the integrator to exceed the maximum output value.

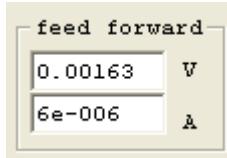

Maximum *error* limits the maximum value allowed to pass through the servo compensator. The units are the same as position units. Typically, when a servo loop is operating normally, its following error is a small value. When some extreme even occurs, such as a sudden large step command, or possibly a large disturbance the error may become very large. In some cases there may be benefit to limiting the error to a reasonable value.

## Tuning Parameters - Motion Profile

The Motion Profile parameters set the maximum allowed velocity (in position units per second), the maximum allowed acceleration (in position units per second<sup>2</sup>), and the maximum allowed jerk (in position units per second<sup>3</sup>). These parameters will be utilized for any independent (non coordinated motion) move command for the axis. The acceleration and jerk also apply to jog commands (move at continuous velocity) for the axis.

## Tuning Parameters - Feed Forward

**KMotion's Feed Forward** may often be used to dramatically reduce the following error in a system. See the [Servo Flow Diagram](#) to see precisely how it is implemented. The idea behind feed forward is to observe the velocity and acceleration of the command signal and anticipate a required output and to apply it without waiting for an error to develop.

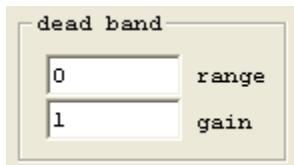

Most motion systems are constructed in manner where some sort of motor force is used to accelerate a mass. In these cases whenever an acceleration is required a force proportional to the acceleration will be required to achieve it. Acceleration feed forward may be used to reduce the amount that the feedback loop must correct. In fact, proper feed forward reduces the requirement on the feedback from the total force required to accelerate the mass, to only the variation in the force required to accelerate the mass.

Similarly most servo systems require some amount of force that is proportional to velocity simply to maintain a constant velocity. This might be due to viscous friction, or possibly motor back emf (electro motive force). In any case velocity feed forward may be used to reduce the demands of the feedback loop resulting in smaller following error.

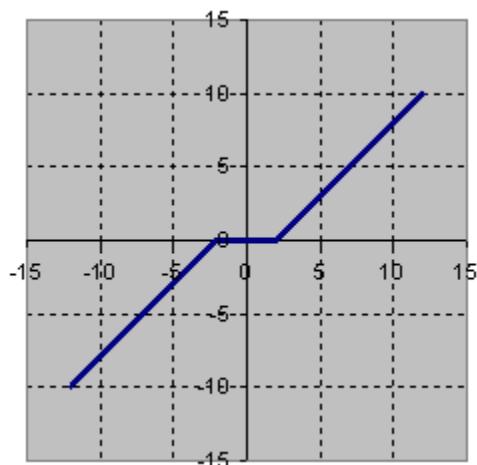

The normal procedure to optimize feed forward is to select plot type - position error, and measure moves using the *Move Command* (Step functions should *not* be used as step functions are instantaneous changes in position that represent infinite velocity and acceleration).

Note that in the [Servo Flow Diagram](#) the feed forward is injected *before* the final [IIR Filter](#). This allows any feed forward waveforms to be conditioned by this filter. Feed forward pulses may be relatively sharp pulses to make rapid accelerations that may often tend to disturb a mechanical resonance in the system. Usually a system with a sharp resonance will benefit from a notch filter to improve the stability and performance of the servo loop. By placing the notch filter as the last filter in the servo loop, the feed forward waveform will also pass through this filter and the result is that the feed forward will cause less excitation of the mechanism than it would otherwise..

## Tuning Parameters - Dead Band

Dead band is used to apply a different gain to the region near zero than the rest of the region. Usually either zero gain or a gain much less than 1 is used within the dead band range. See the [Servo Flow Diagram](#) for the exact location of where the dead band is inserted. Dead band is a means of introducing "slop" into a system. This usually results in less accuracy and performance, but may reduce or eliminate limit cycle oscillations while resting at the target position.

The values shown (range = 0, gain = 1) are used to defeat any dead band. The chart shows the resulting input/output for range = 2, gain = 0. The slope of the graph is always 1 outside of the specified +/- range, and the specified gain with the +/- range.

## Measurement

To perform a measurement and display the response, select the time duration to gather data, and the move or step size to perform, and press either the Move or Step buttons. If the axis is currently enabled, it will be disabled, all parameters from all screens will be downloaded, the axis will be enabled, the move or step will be performed while the data is gathered, the data will then be uploaded and plotted.

A **Move** will hold position for a short time, perform a motion of the specified amount from the current location, pause for a short time, and then a second motion back to the original location.

A **Step** will hold position for a short time, perform a step of the specified amount from the current location, pause for a short time, and then a second step back to the original location.

The maximum time that data may be collected is 3.5 seconds (3.5 seconds / 90 $\mu$ s = 38,888 data points). Note that collecting data at this rate allows zooming while still maintaining high resolution.

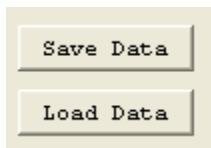

## Axis Control

The Axis Control buttons are present to conveniently disable (Kill), Zero, or Enable an axis. If the axis becomes unstable (possibly due to a gain setting too high), the Kill button may be used to disable the axis, the gain might then be reduced, and then the axis may be enabled. The Enable button downloads all parameters from all screens before enabling the axis in the same manner as the [Measurement](#) buttons described above.

*Note for brushless output modes that commutate the motor based on the current position, Zeroing the position may adversely affect the commutation.*

## Save/Load Data

The Save/Load Data buttons allow the captured Step Plot to be saved to a text file and re-loaded at a later time. The text file format also allows the data to be imported into some other program for display or analysis. The file format consists of one line of header followed by one line of 5 comma separated values, one line for each sample. The values are:

1. Sample Number
2. Time, Seconds
3. Command
4. Position
5. Output

Example of data file follows:

```
Sample,Time,Command,Position,Output
0,0,5,5,-0.3301919
1,9e-005,5,5,-0.3300979
2,0.00018,5,5,-0.3300258
3,0.00027,5,5,-0.3299877
4,0.00036,5,5,-0.3299999
5,0.00045,5,5,-0.3300253

The **Console Screen** displays messages from the DSP and the PC. The Console window retains the last 1000 lines of text. After more than 1000 lines are displayed the earliest messages scroll off into a permanent text file (**LogFile.txt**) in the **KMotion\Data** subdirectory.

To Send a command to the DSP enter the text string in the bottom command cell and press the **Send** button.

Selecting the  **Multi** Check box changes from a single command line to multiple command lines, see below. This allows several commands to be entered and then easily sent with a single push button.

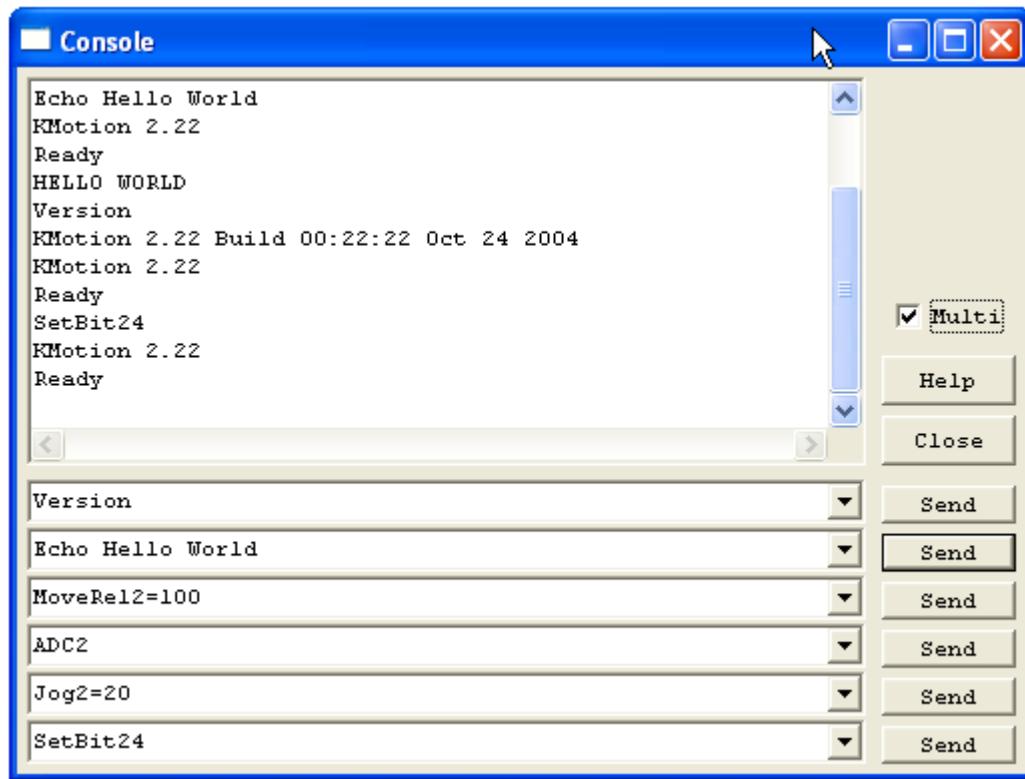

Multiple commands may be entered on a single line by separating the commands with a semicolon. For Example:

SetBit46;SetBit47

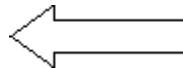

```

#7 0.00	#7 0	<input type="checkbox"/>	Encoder No Output	<input type="checkbox"/>

[Help](#) [Close](#)

The **Axis Screen** displays Axis Status including:

- Current Commanded Destination
- Current Measured Position
- Whether the axis is currently enabled
- Input Mode
- Output Mode
- Done Status (no independent Move or Jog in progress)
- Current Bar Graph (if current sensing is available for the axis)

Clicking on Enable will enable or disable the axis without downloading any parameter settings to KFLOP.

## KFLOP Summary

### Eight-Axis, DSP/FPGA-based Motion Controller

DynoMotion's KFLOP card combines a 1.2 GFLOP DSP (TMS320C6722), FPGA, USB, and a PC-based development environment to create a versatile and programmable motion solution. Designed for up to eight-axes control, KFLOP provides advanced control for torque, speed, and position for any mix of stepper, DC brushless, and DC brush motors. KFLOP uses flash memory to store and run multiple-thread compiled C code on a 1.2 GFLOP processor with native 64-bit floating point support for stand-alone operation. A PC connected with a USB cable can be used for control and monitoring.

The included PC-based integrated development environment combines configuration, status, programming, and advanced diagnostic and tuning tools such as Bode plots and signal filtering. GCode support allows coordinated moves between axes. Libraries for controlling the KFLOP card via Visual C++ and Visual Basic are included, as well as a free C compiler. Thread-safe operation allows the IDE to be used in conjunction with a user application for control and debugging.

The KFLOP packs a lot of IO into its 5.0 x 3.5 in package. KFLOP offers 45 Bi-directional I/O bits, shared between dedicated IO and user-defined I/O.

<http://dynamotion.com>, Calabasas, CA. [sales@dynamotion.com]

# THANK YOU!!

for purchasing KFLOP  
**1.2 GFLOP Motion Controller**  
**by Dymotion, Inc.**

[www.dymotion.com](http://www.dymotion.com)

Email: support@dymotion.com

Please download and install the latest software from

<http://dymotion.com/Software/Download.html>

The installation will create a Windows™ Start button link to further help and to the **KMotion** Setup and Tuning Application.

## QuickStart

Remove the KFLOP Board from the anti-static packaging in a static safe environment.

***Note: immediately before touching any electronic component, always discharge any static electricity you may have by touching an earth ground, such as the metal chassis of a PC.***

KFLOP may operate powered from the USB by inserting J3. Total power must be < 0.5A for USB powered operation. Otherwise remove J3 and connect a +5V power supply to the **KMotion** 4 pin Molex connector. This connector is the same Pinout as a PC Disk Drive power connector. A PC power supply makes an excellent low cost power source for **KFLOP**. The +12V is not required for operation, it is routed internally through the board to several of the connectors. See the on-line help section titled *Hardware/Connector Description* for more information.

***Note: KFLOP may at times draw as little as 0.25 Amps from the +5V supply. Some PC power supplies will not function without a minimum load. In these cases an appropriate power resistor (~10 ohm 5 Watt) should be added across the +5V. Additionally, most ATX power supplies require pins 14 and 15 on the main 20 pin power connector to be shorted.***

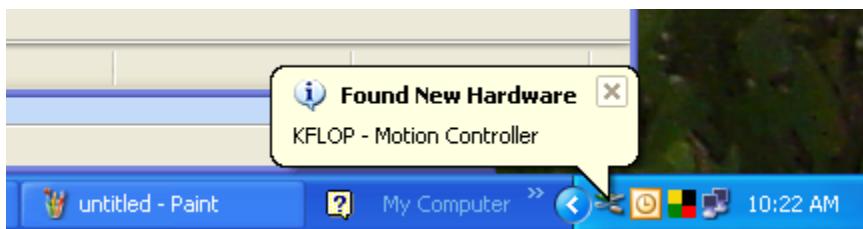

***Note: it is NOT recommended to use the same power supply that is powering your PC and Hard drives to power the KFLOP. Motor noise and power surges have the possibility to cause damage or loss of data within the PC.***

Connect the USB or turn on the +5V supply. Two green LEDs should blink rapidly for a few seconds (**KFLOP** is checking if the Host is requesting a Flash Recovery during this time), and then the LEDs should remain steady.

Now connect a USB cable from **KFLOP** to your PC and follow the USB Driver instructions below.

## USB Installation

The first time the **KFLOP** board is connected to a computer's USB port this message should be displayed near the Windows™ Task Bar.

Shortly thereafter, the New Hardware Wizard Should appear.

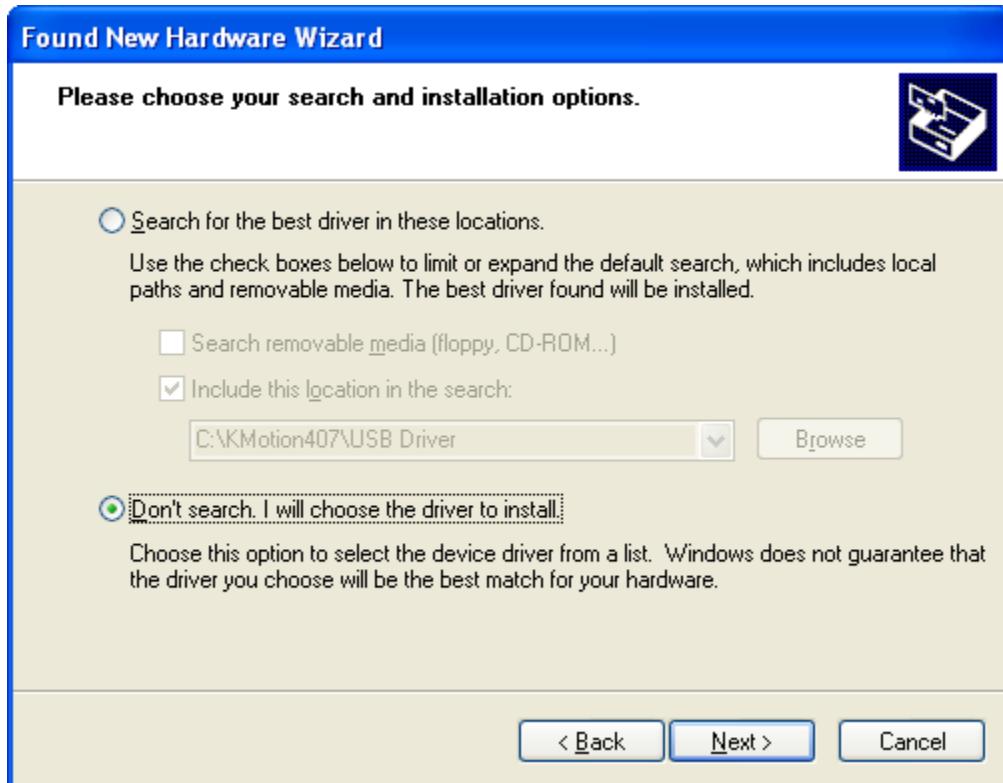

Select "**Install from a specific location (Advanced)**" and select **Next**.

If you haven't already, download and install the complete **KFLOP** Software including drivers available at:

<http://dynamotion.com/Software/Download.html>

Select: "Don't search. I will choose the driver to install" and click **Next**

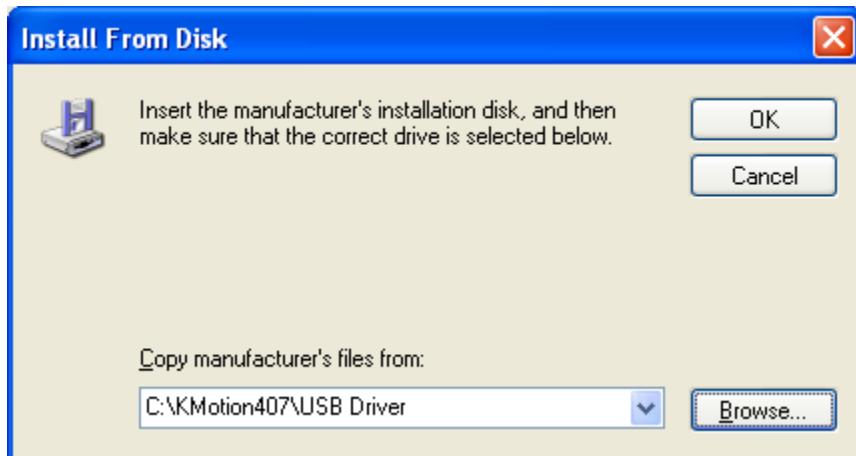

Select: "Have Disk..."

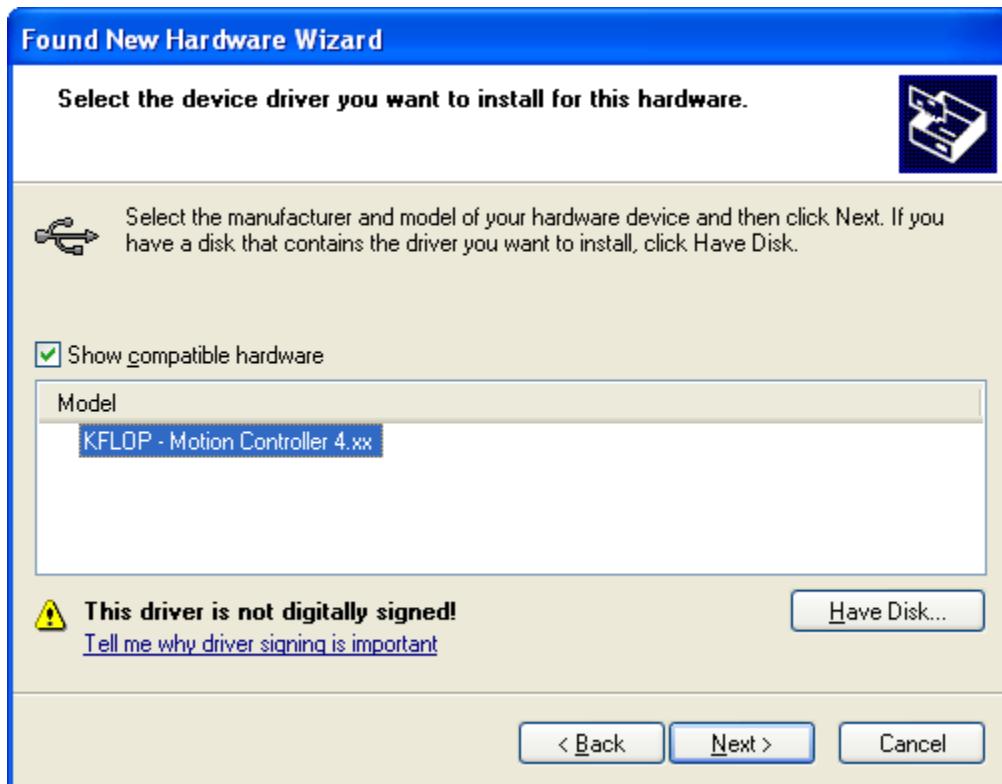

Browse to within the subdirectory where you selected the **KFLOP** Software to be installed to the "USB DRIVER" subdirectory.

(If the software was installed into the default subdirectory, the location would be: **C:\KFLOP4xx\USB DRIVER**)

Click **OK**

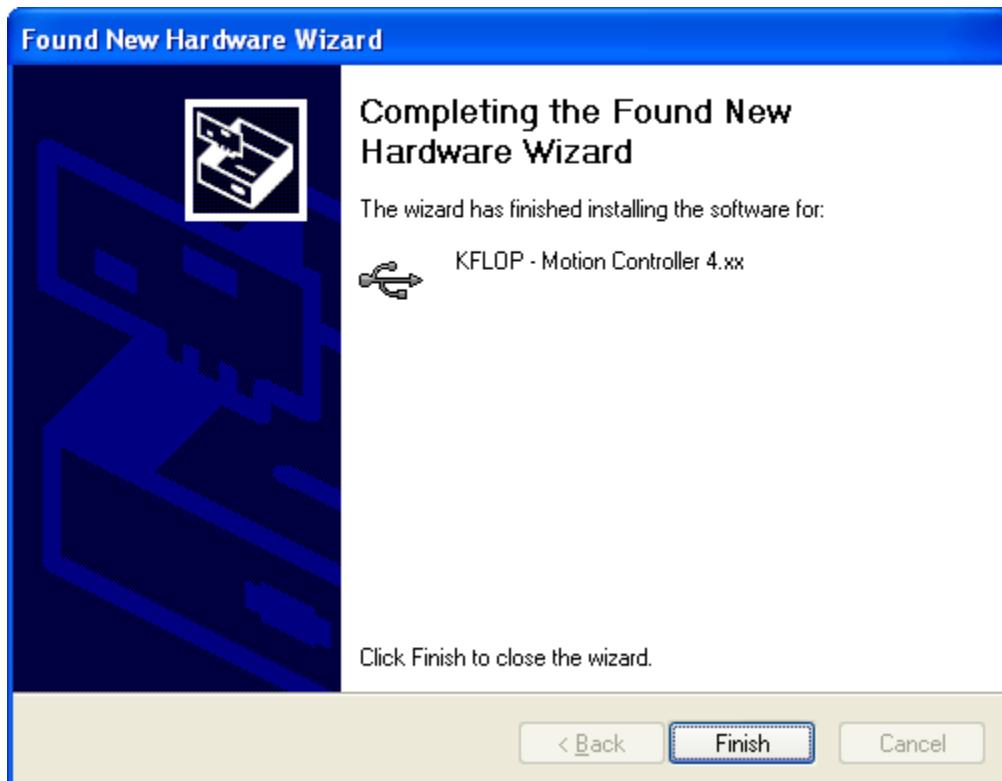

Select "KFLOP - Motion Controller 4.xx" and select **Next**

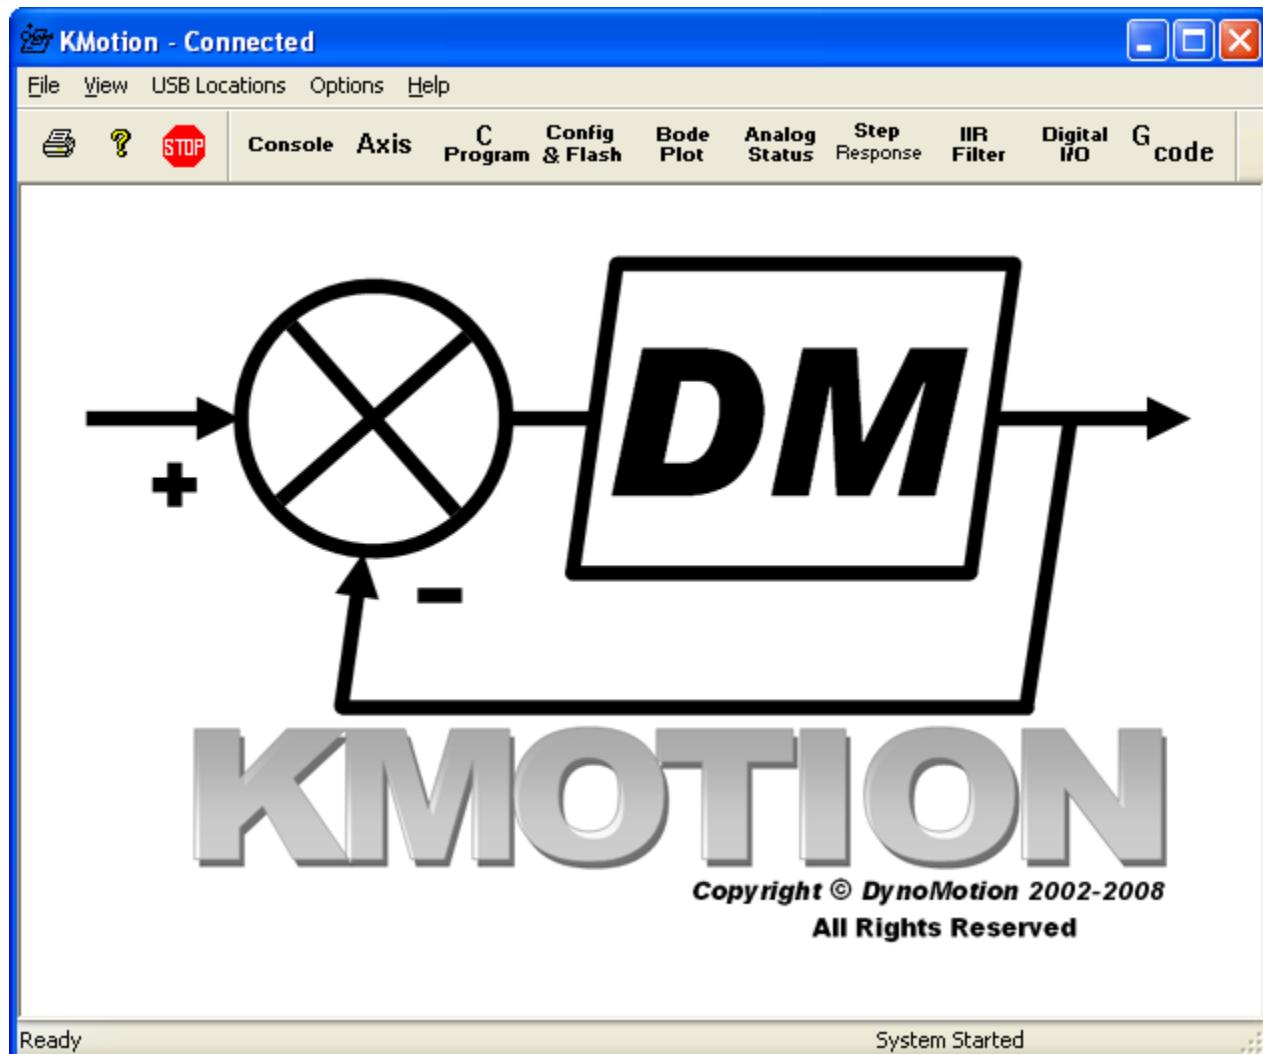

If this screen appears select **Continue Anyway**.

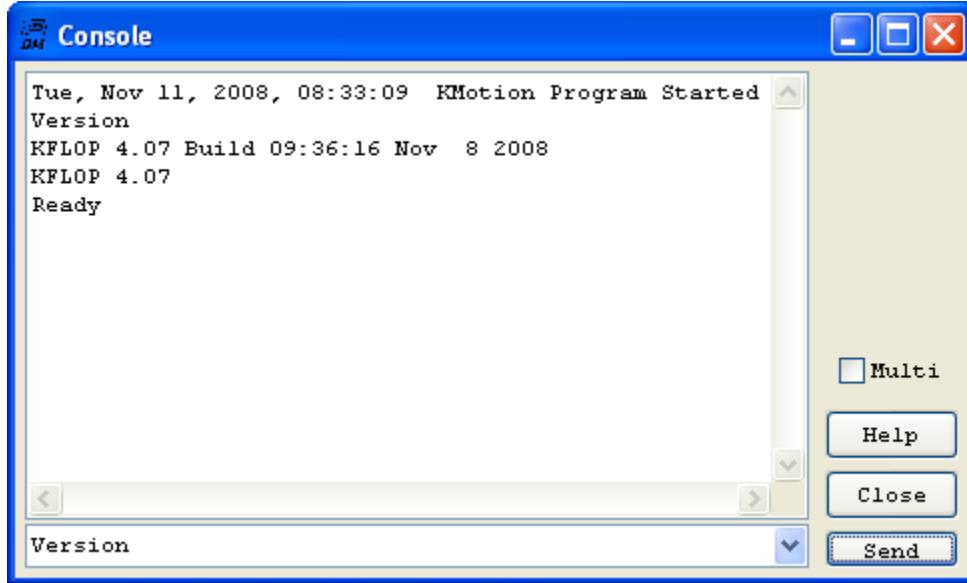

If successful, the above screen should appear. Click **Finish**.

The **KFLOP** Board is now ready for use. To verify proper USB connection to the KFLOP Board, use the Windows™ Start Button to launch the **KMotion** Application.

At the main tool bar select the "Console" button to Display the Console Screen.

Enter the “Version” command and press the “Send” button to send the ‘Version’ command to the **KFLOP** Board. The following should be displayed indicating successful communication between the PC and **KFLOP** Board.

**KFLOP 4.07 Build 09:36:16 Nov 8 2008**  
**KFLOP 4.07**  
**Ready**

See the On-Line help for more information on how to connect your motors drives, enter console script commands, compile and run C Programs, execute G Code, and much more!!!

## Board Layout

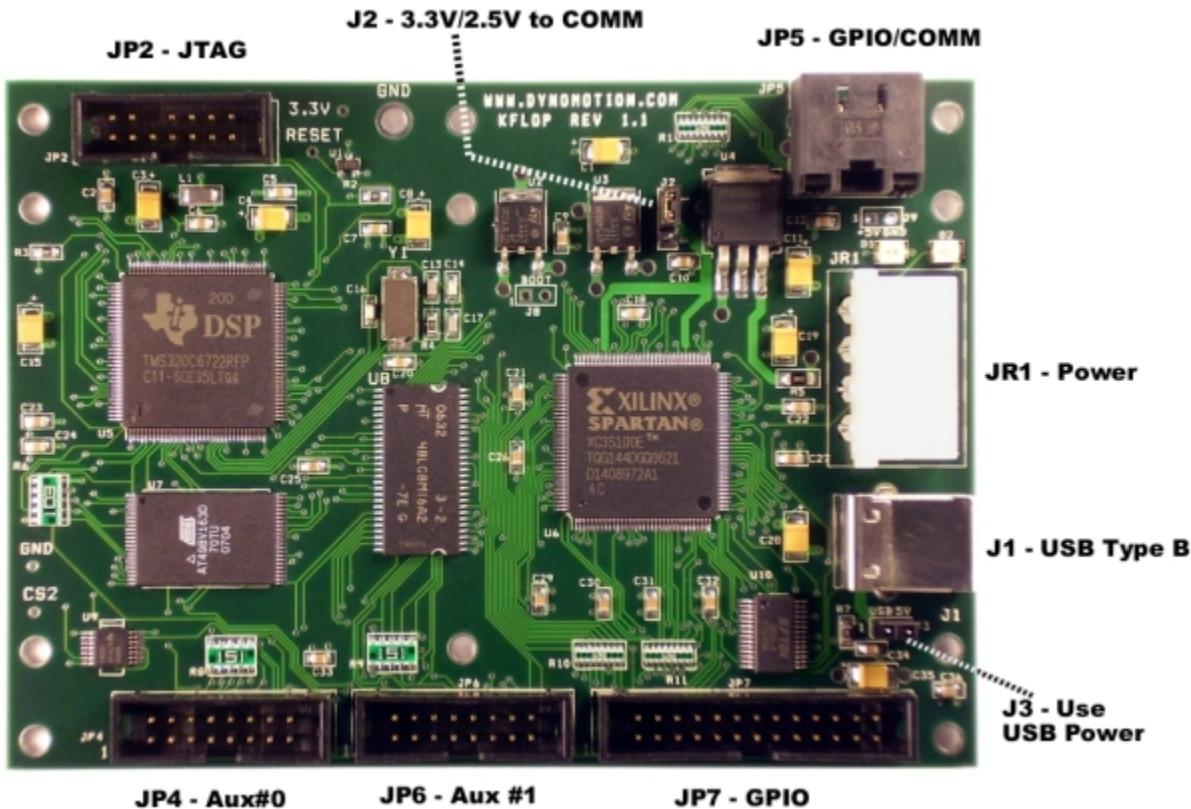

## Block Diagram

## KFLOP - Connector Pinouts

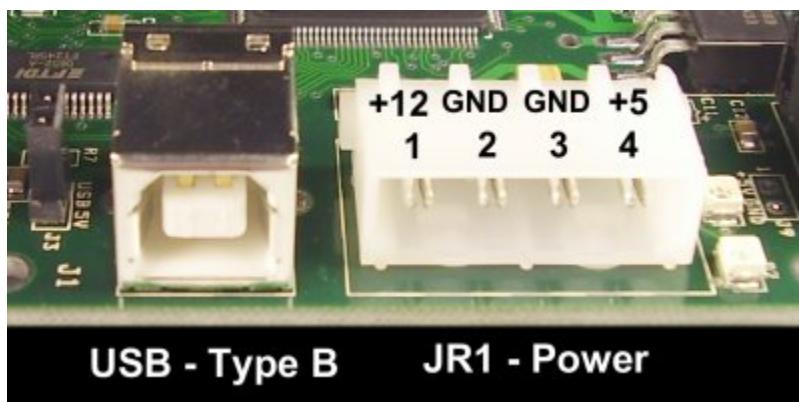

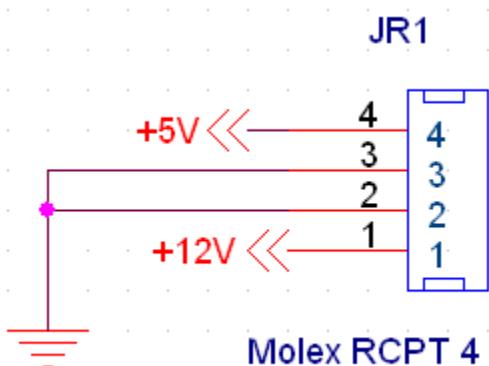

### **JR1 - +5V Power (regulated +/- 5%)**

Typical current = 0.35Amps with no user I/O connected. More current may be required dependent on the amount of Digital I/O and option boards. +5V @ 2.5A should be more than sufficient under all conditions. The +12V input is not used internally by the board, but is routed to pins on the JP4, JP6, and JP7 connectors for the convenience of the user. +5V power is also routed to the same connectors. 5V power may be applied at whichever connector is more convenient. This connector is rated for 6.5Amps per connection.

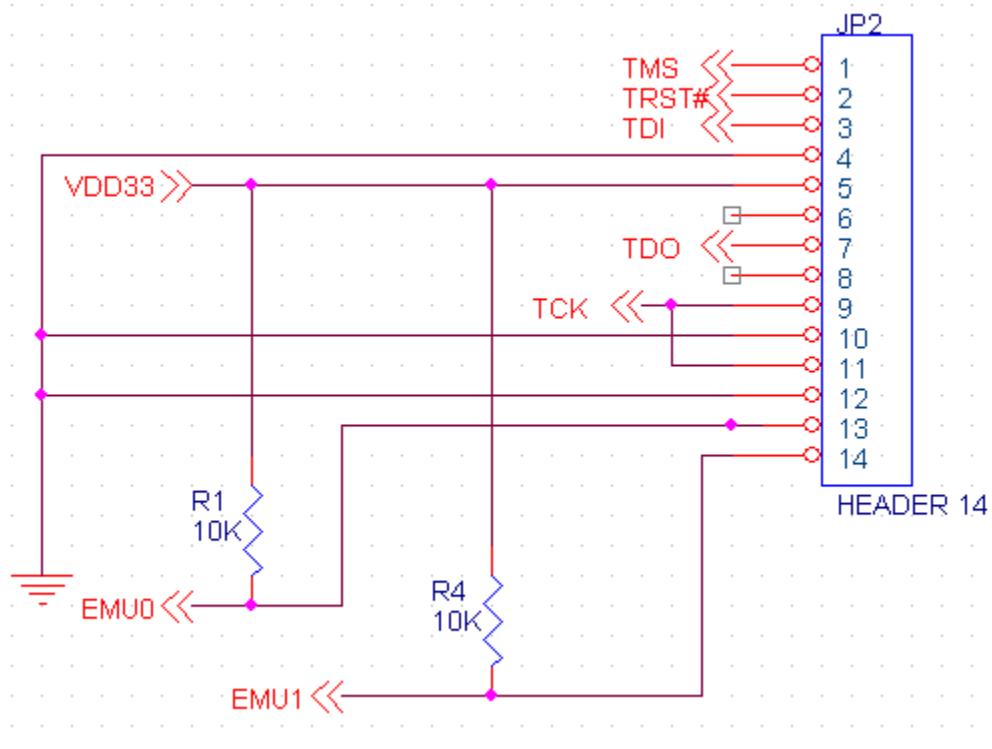

This connector is a standard PC-disk drive power connector which makes it easy to drive the board with an inexpensive PC power supply.

Under some conditions USB power may be used to avoid requiring an external +5V power supply connection. USB specifies a maximum of 500ma may be drawn from the USB cable. KFLOP itself consumes 350ma. If external IO draws less than the remaining 150ma USB supplied power may be used. To utilize USB power connect Jumper J3 and do not supply +5V into any of the KFLOP connectors.

### JP2 - JTAG

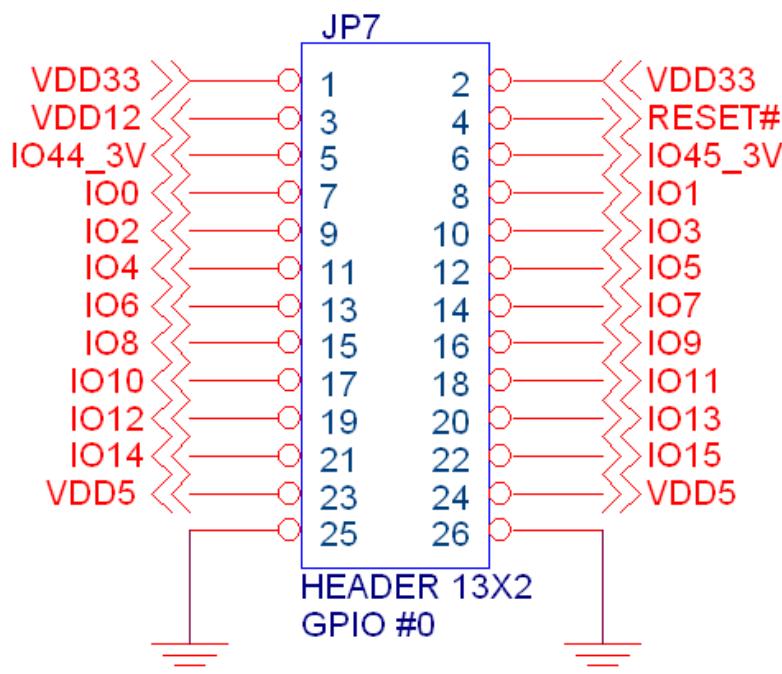

This connector is only used for advanced debugging using an XDS510 JTAG type in circuit emulator. A small amount of regulated 3.3V (<0.5 Amp) is available on this connector if needed for external use.

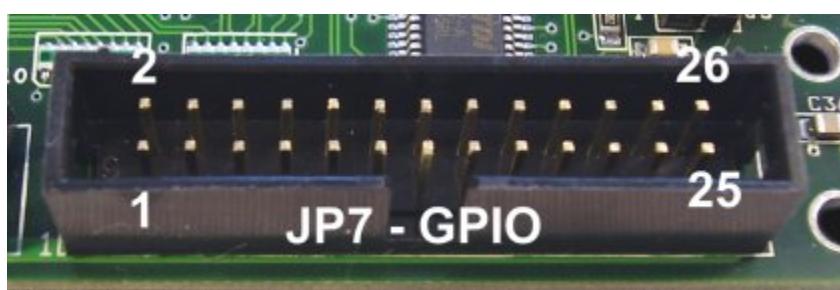

### ***JP7 - Digital IO***

18 LVTTL bi-directional digital I/O, and +5, +15, -15 power supply outputs. Many Digital I/O bits are pre-defined as encoder, home, or limit inputs (see table below) but if not required for the particular application may be used as general purpose I/O. Digital Outputs may sink/source 10 ma. Digital I/O is LVTTL (3.3V) but is 5 V tolerant.

***Caution! This connector contains 12V signals. Shorts to low voltage pins will cause permanent damage to the board!***

NOTE: DO NOT APPLY  
5V to \_3V INPUTS

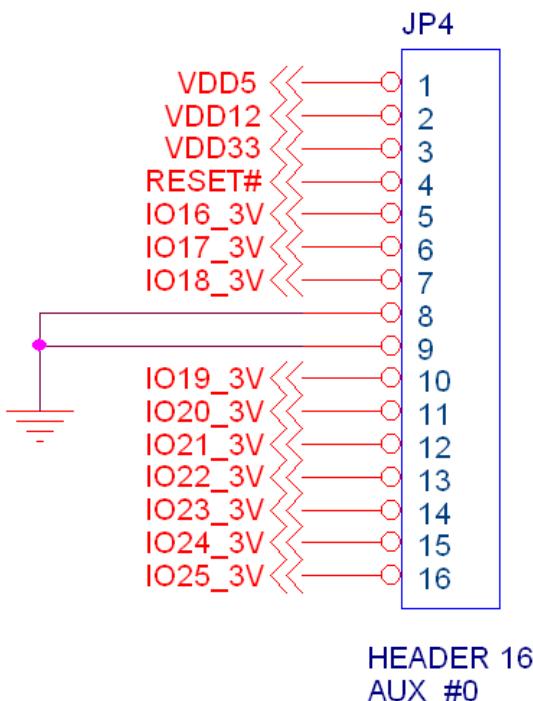

Pin	Name	Description
1	VDD33	+3.3 Volts Output
2	VDD33	+3.3 Volts Output
3	VDD12	+12 Volts Output
4	RESET#	Power up Reset (low true) output
5	IO44	Gen Purpose LVTTL I/O (3.3V Only)
6	IO45	Gen Purpose LVTTL I/O (3.3V Only)
7	IO0	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 0 Encoder Input Phase A
8	IO1	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 0 Encoder Input Phase B
9	IO2	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 1 Encoder Input Phase A
10	IO3	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 1 Encoder Input Phase B
11	IO4	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 2 Encoder Input Phase A
12	IO5	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 2 Encoder Input Phase B
13	IO6	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 3 Encoder Input Phase A
14	IO7	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 3 Encoder Input Phase B
15	IO8	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 0 Home (or Step 0 output)
16	IO9	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 1 Home (or Dir 0 output)
17	IO10	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 2 Home (or Step 1 output)
18	IO11	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 3 Home (or Dir 1 output)
19	IO12	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 0 + Limit (or Step 2 output)
20	IO13	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 0 - Limit (or Dir 2 output)
21	IO14	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 1 + Limit (or Step 3 output)
22	IO15	Gen Purpose LVTTL I/O (5V Tolerant) or Axis 1 - Limit (or Dir 3 output)
23	VDD5	+5 Volts Output
24	VDD5	+5 Volts Output
25	GND	Digital Ground
26	GND	Digital Ground

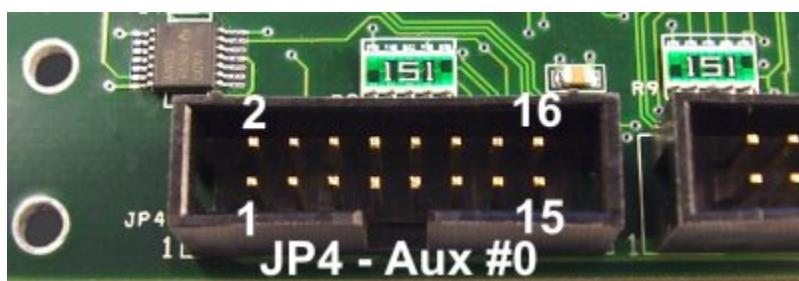

**Note:** Homes and Limits are recommendations only. Any input may be used.

## JP4 - Aux Connector #0

Auxiliary connector which supplies power, reset, and 10 digital I/O (LVTTL 3.3V only) which is normally connected to optional expansion daughter boards (ie. SnapAmp 1000). If no expansion module is required, these digital I/O may be used for general purpose use. The first 8 IO (IO16-IO23) contain 150ohm termination resistors (pull downs).

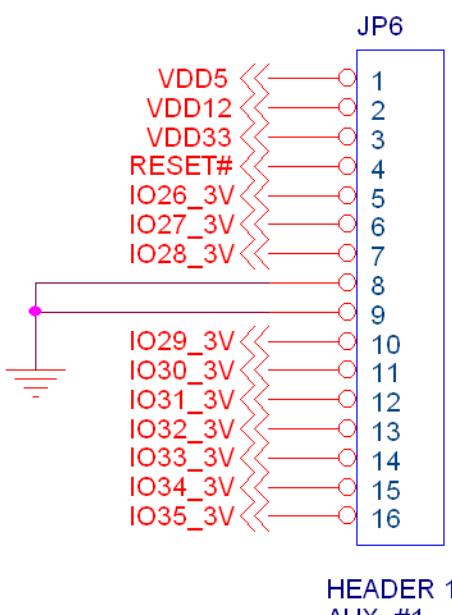

NOTE: DO NOT APPLY  
5V to \_3V INPUTS

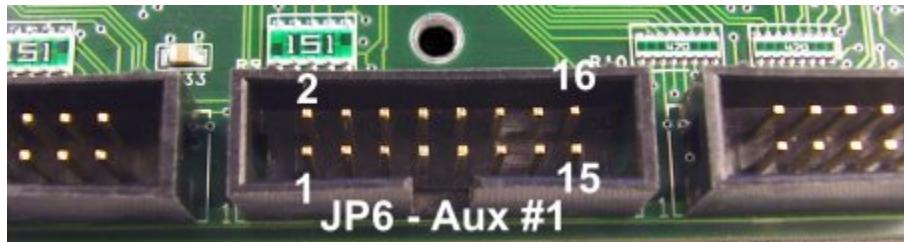

Pin	Name	Description
1	VDD5	+5 Volts Output
2	VDD12	+12 Volts Output
3	VDD33	+3.3 Volts Output
4	RESET#	Power up Reset (low true) output
5	IO16	Gen Purpose LVTTL I/O (3.3V Only)
6	IO17	Gen Purpose LVTTL I/O (3.3V Only)
7	IO18	Gen Purpose LVTTL I/O (3.3V Only)
8	GND	Digital Ground
9	GND	Digital Ground
10	IO19	Gen Purpose LVTTL I/O (3.3V Only)
11	IO20	Gen Purpose LVTTL I/O (3.3V Only)
12	IO21	Gen Purpose LVTTL I/O (3.3V Only)
13	IO22	Gen Purpose LVTTL I/O (3.3V Only)
14	IO23	Gen Purpose LVTTL I/O (3.3V Only)
15	IO24	Gen Purpose LVTTL I/O (3.3V Only)
16	IO25	Gen Purpose LVTTL I/O (3.3V Only)

### JP6 - Aux Connector #1

Auxiliary connector which supplies power, reset, and 10 digital I/O (LVTTL 3.3V only) which is normally connected to optional expansion daughter boards (ie. SnapAmp 1000). If no expansion module is required, these digital I/O may be used for general purpose use. The first 8 IO (IO26-IO33) contain 150ohm termination resistors (pull downs).

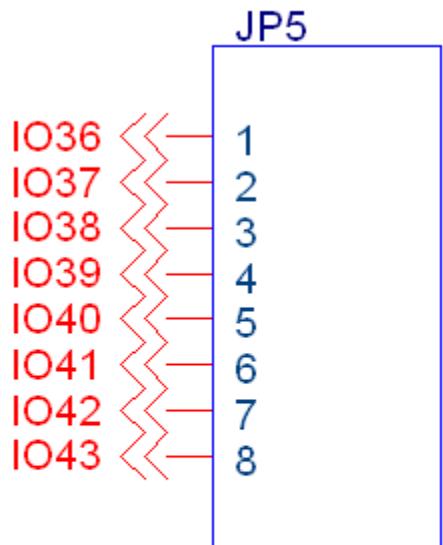

NOTE: DO NOT APPLY  
5V to \_3V INPUTS

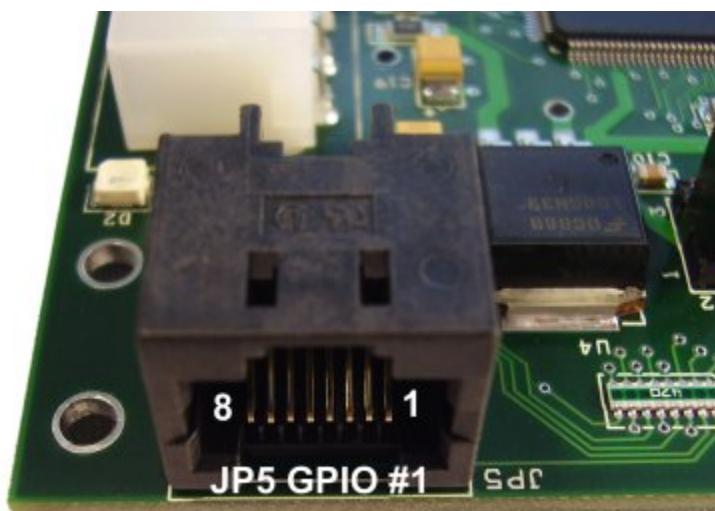

Pin	Name	Description
1	VDD5	+5 Volts Output
2	VDD12	+12 Volts Output
3	VDD33	+3.3 Volts Output
4	RESET#	Power up Reset (low true) output
5	IO26	Gen Purpose LVTTL I/O (3.3V Only) or PWM0 out
6	IO27	Gen Purpose LVTTL I/O (3.3V Only) or PWM1 out
7	IO28	Gen Purpose LVTTL I/O (3.3V Only) or PWM2 out
8	GND	Digital Ground
9	GND	Digital Ground
10	IO29	Gen Purpose LVTTL I/O (3.3V Only) or PWM3 out
11	IO30	Gen Purpose LVTTL I/O (3.3V Only) or PWM4 out
12	IO31	Gen Purpose LVTTL I/O (3.3V Only) or PWM5 out
13	IO32	Gen Purpose LVTTL I/O (3.3V Only) or PWM6 out
14	IO33	Gen Purpose LVTTL I/O (3.3V Only) or PWM7 out
15	IO34	Gen Purpose LVTTL I/O (3.3V Only)
16	IO35	Gen Purpose LVTTL I/O (3.3V Only)

### **JP5 - GPIO #1 / LV Differential Connector**

Low Voltage Differential RJ45 Connector. This connector is intended for high-speed low-voltage differential communication over a twisted pair cable use. However it may also be used as 8 General Purpose digital I/O (LVTTL 5V Tolerant)

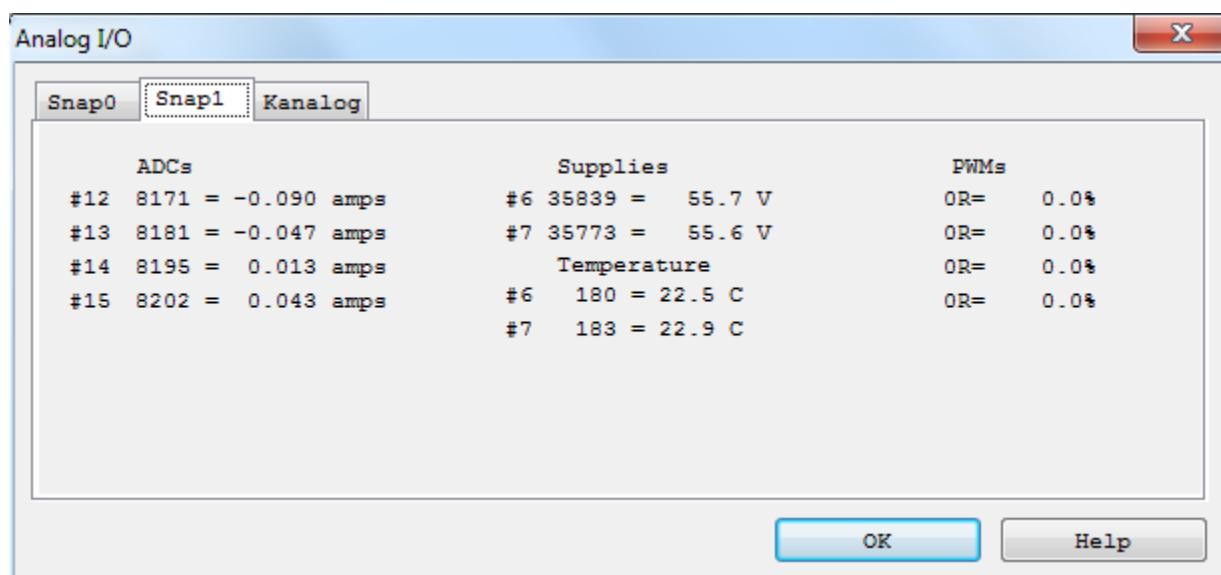

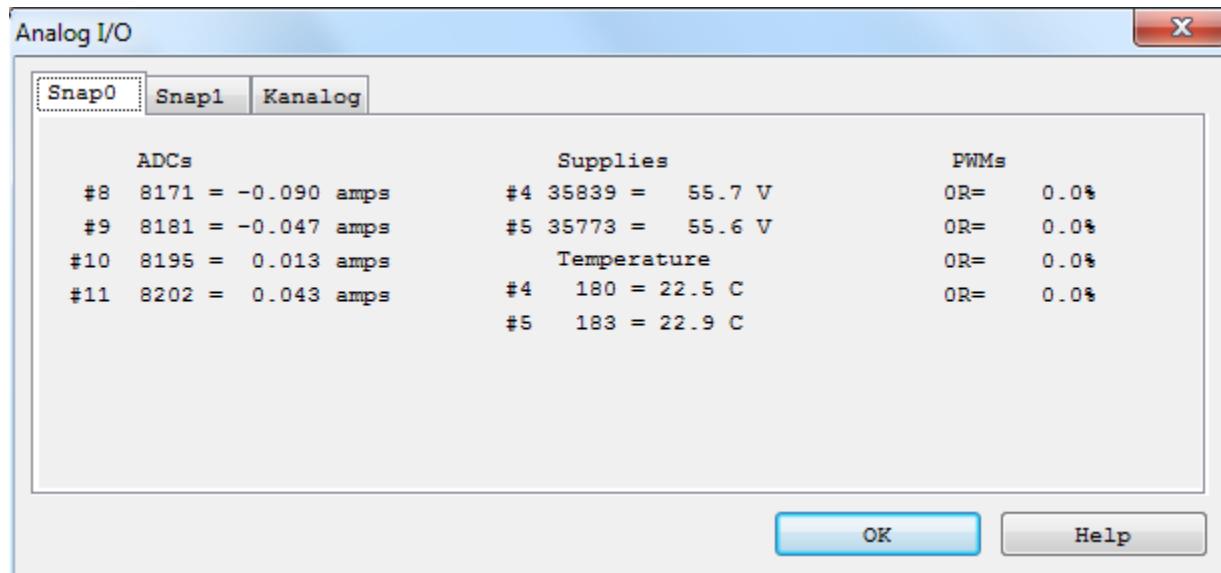

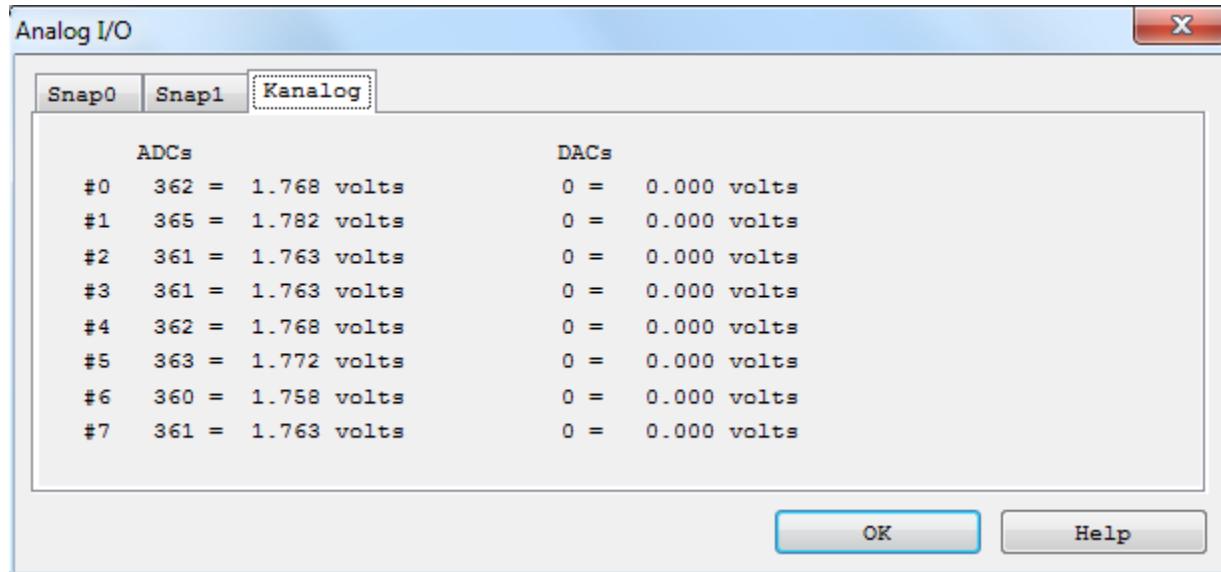

RJHSE-5080  
GPIO #1  
5V TOLERANT

Pin	Name	Description
1	IO36	Gen Purpose LVTTL I/O (5V Tolerant) or (or Step 4 output) or (Axis 4 Encoder Input Phase A)
2	IO37	Gen Purpose LVTTL I/O (5V Tolerant) or (or Dir 4 output) or (Axis 4 Encoder Input Phase B)
3	IO38	Gen Purpose LVTTL I/O (5V Tolerant) or (or Step 5 output) or (Axis 5 Encoder Input Phase A)
4	IO39	Gen Purpose LVTTL I/O (5V Tolerant) or (or Dir 5 output) or (Axis 5 Encoder Input Phase B)
5	IO40	Gen Purpose LVTTL I/O (5V Tolerant) or (or Step 6 output) or (Axis 6 Encoder Input Phase A)
6	IO41	Gen Purpose LVTTL I/O (5V Tolerant) or (or Dir 6 output) or (Axis 6 Encoder Input Phase B)
7	IO42	Gen Purpose LVTTL I/O (5V Tolerant) or (or Step 7 output) or (Axis 7 Encoder Input Phase A)
8	IO43	Gen Purpose LVTTL I/O (5V Tolerant) or (or Dir 7 output) or (Axis 7 Encoder Input Phase B)

## Analog I/O Status Screen

The **Analog I/O Status Screen** displays various analog measurements and commands including:

- Kanalog DAC Settings
- Kanalog ADC Readings
- SnapAmp Measured current flow per motor coil
- SnapAmp Power Supply Voltages
- SnapAmp Mosfet Temperatures
- SnapAmp PWM power amp settings

KFLOP itself has no Analog capability and when operated alone with no option cards the Analog I/O Screen will not display. If one or two **SnapAmp** option boards are installed and checked on the option menu, tabs will allow display **of SnapAmp** Status. Current measurement for each full bridge (motor coil), Power supply voltage for each side, Temperature of each side, and PWM setting for each PWM. If Kanalog is installed and checked on the option menu a tab will allow displaying Kanalog Analog Status.

### PWM's

The state of each **SnapAmp's** four PWM (Pulse Width Modulators) are displayed in the top right area of the status screen. The PWM's are connected to *Full Bridge Drivers* to allow direct control of various motors or loads. See the description of [KMotion's Power Amplifiers and PWM's](#) for details. The PWM's may operate independently to drive a full bridge driver, or they may function as a pair of PWM's connected to a pair of Full Bridge drivers to drive a 4 phase stepper motor or a [3 phase load](#).

PWMs may be assigned to an axis by changing the OutputChan0 and OutputChan1 parameters for an axis. Only consecutive even and odd PWMS may be paired to drive a 3 or 4 phase phase load.

There are several possible modes for each PWM channels:

- Normal Independent
- Recirculating Independent
- 3 Phase - paired
- Current Feedback

If a PWM channel is operating in Normal mode, the PWM channel status will show the value in counts (-255 ... +255) and the percent of full scale.

If a PWM channel is operating in Recirculating mode, the PWM channel status will show the value in counts (-511 ... +511), followed by an "R", and the percent of full scale.

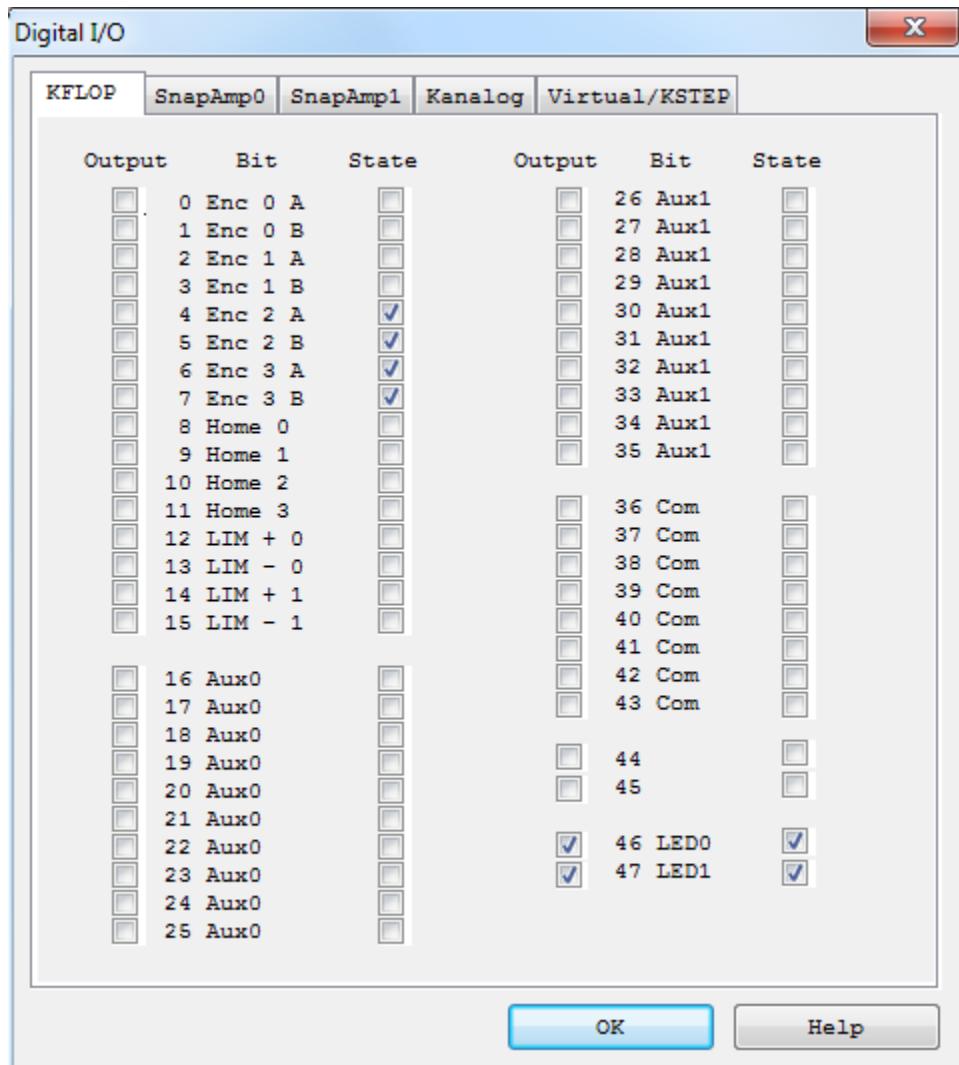

A PWM channel may also operate in current loop mode. In current loop mode the PWM duty cycle is automatically adjusted in order to maintain the commanded current. The PWM channel status will show the command value in counts (-4095 ... +4095), followed by a "C", and the percent of full scale.

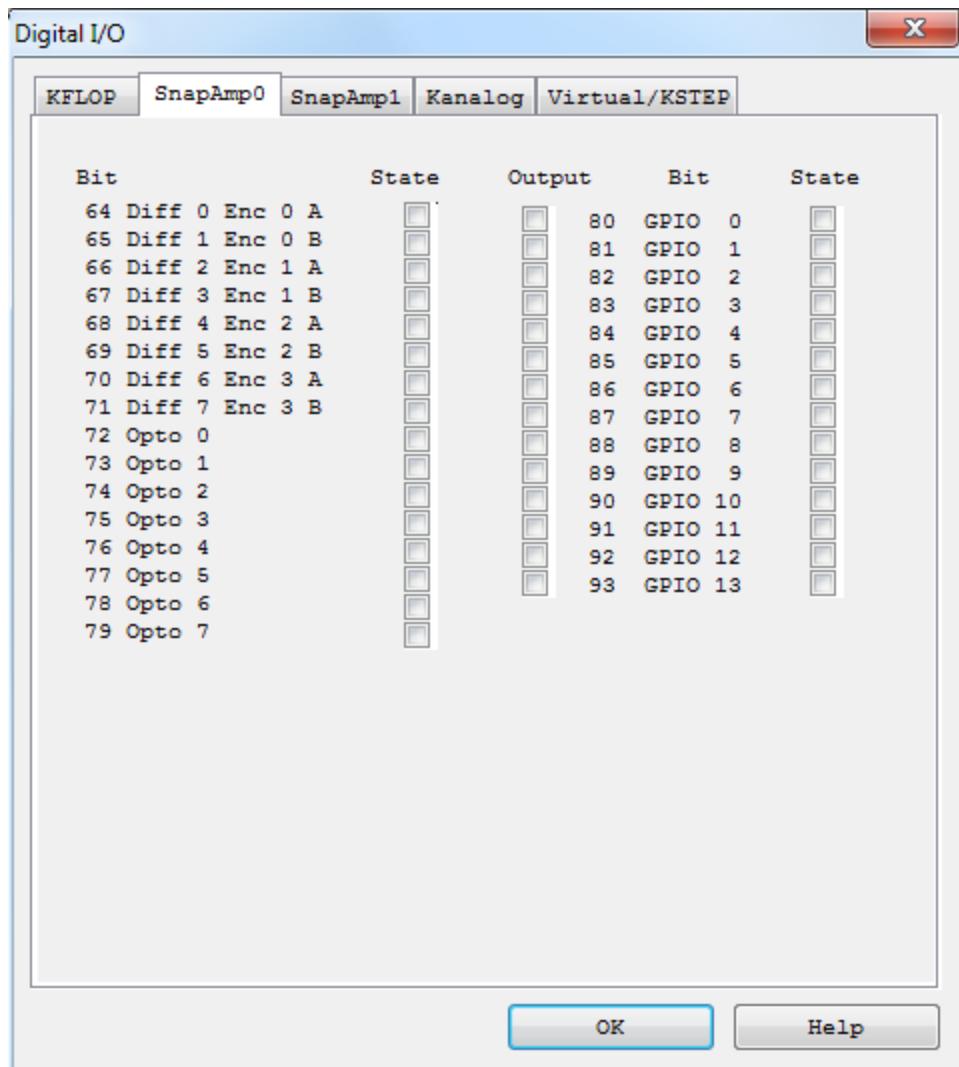

If a pair of PWM channels is operating in 3 Phase mode, the PWM channel status will show the value in counts (-230 ... 230) after the first PWM channel and the phase angle in degrees after second PWM channel.

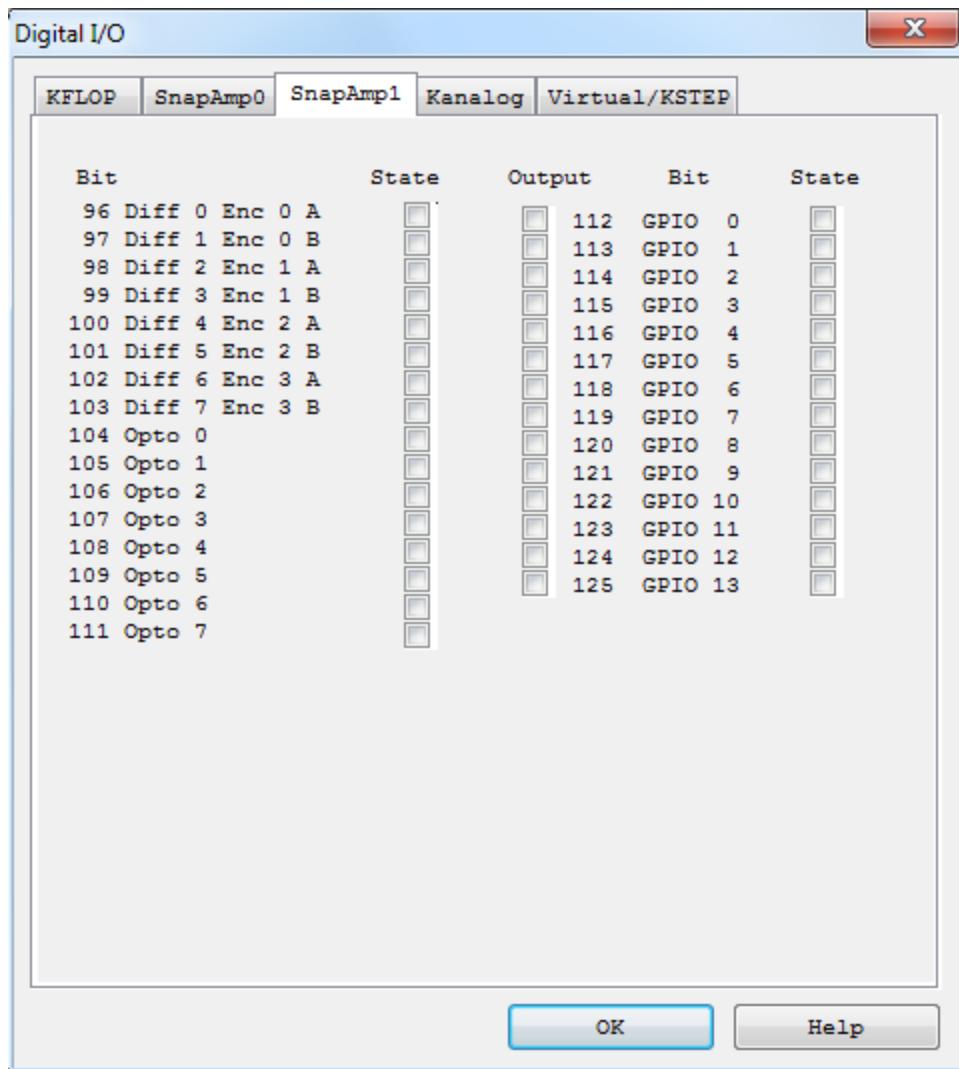

The example status below shows PWM channels 8 and 9 operating in 3 phase mode, PWM channel 10 operating in Normal mode, and PWM channels 11 operating in Recirculating mode.

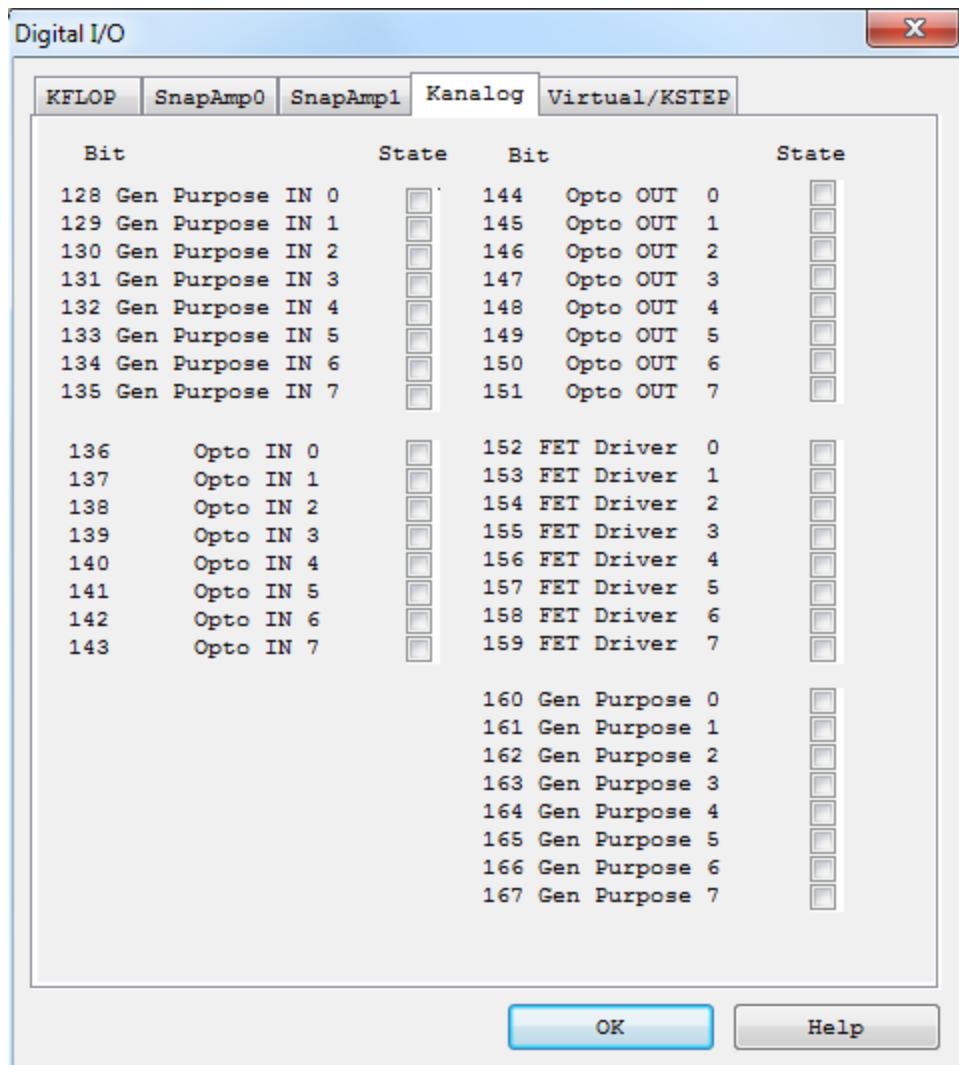

```
PWMs
100 = 43.5%
120 degrees
50 = 19.5%
200R= 39.1%
```

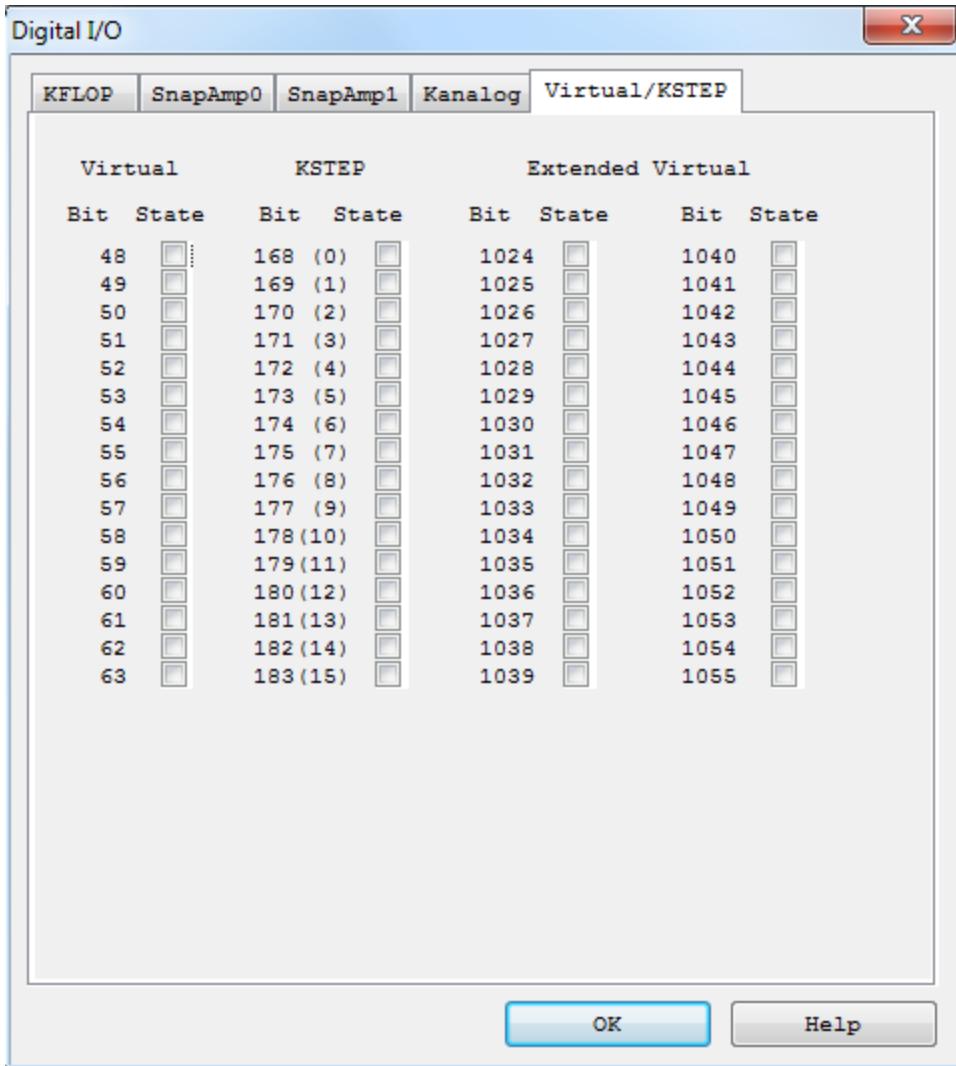

## Digital I/O Screen

The **Digital I/O Screen** displays and allows changes to the current state of **KFLOP** digital I/O bits. Digital IO bits are present on the **KFLOP** as well as any additional option cards (such as with two SnapAmps or Kanalog as shown above). IO bits are numbered 0-167.

**KMotion** has a number of digital I/O bits that may be used as GPIO (General Purpose Inputs or Outputs) or as specific dedicated functions (ie. encoder inputs). There are 46 bits that may be utilized as GPIO (bits 0 - 45). Each bit may be independently defined as either an input or an output. On Power UP **KMotion** defines all I/O as inputs by default. Any bit may be configured as an output by checking the corresponding box in the "Output" columns. Alternately, the bits may be configured by a C program running within the **KMotion** (See [SetBitDirection\(\)](#)) or by Script commands (See [SetBitDirection](#)) sent to the **KMotion**.

**KFLOP** bits 0-15 are connected to the JP7 connector normally which may be used to connect to auxiliary option boards such as Kanalog. These bits are available for User use if no option cards are requiring them in the system **If they are used to communicate to an option board, care should be taken to not issue any User IO commands to these bits.**

**1KFLOP** bits 16 - 25 are connected to the Aux#0 connector normally used as a high-speed communication bus to connect to auxiliary option boards such as SnapAmps. These bits are available for User use if no option cards are requiring them in the system. **If they are used to communicate to an option board, care should be taken to not issue any User IO commands to these bits.**

The State of each I/O bit may be observed in the corresponding checkbox under the "State" columns. If the bit is defined as an output, clicking on the "State" checkbox will toggle the bit. Alternately, the bits may be read, set, or cleared by a C program running within the **KMotion** (See [ReadBit\(\)](#), [SetBit\(\)](#), [ClearBit\(\)](#), or [SetStateBit\(\)](#)) or by Script commands (See [ReadBit](#), [SetBit](#), [ClearBit](#), or [SetStateBit](#)) sent to the **KMotion**.

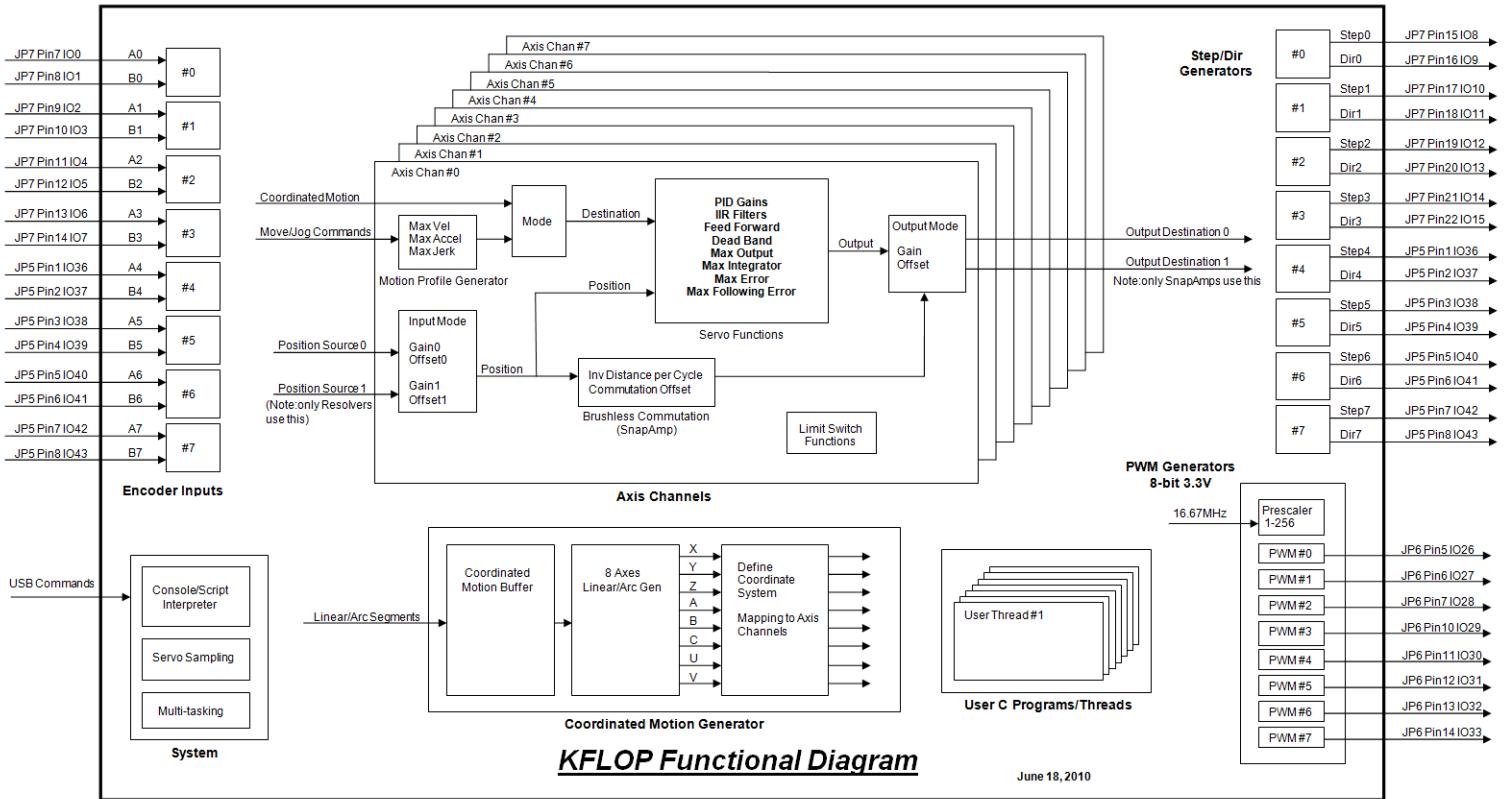

Additionally, *buffered* commands may change the state of Digital I/O bits. *Buffered* I/O commands are I/O commands that are inserted into the coordinated motion buffer. When it is required that I/O bits be changed at exact times within a motion sequence, *buffered* I/O commands may be inserted into the motion buffer (see [SetBitBuf](#), [ClearBitBuf](#), and [SetStateBitBuf](#)). In this case the I/O commands occur when they are encountered within the motion sequence. The **KMotion** GCode interpreter allows buffered I/O commands to be inserted within motion sequences by using a special form of GCode comment (See [buffered GCode Commands](#)).

See the [KFLOP Hardware Connector Descriptions](#), [SnapAmp Hardware Connector Descriptions](#), or [Kanalog HardwareConnector Descriptions](#) for which IO bits are connected to the various connectors.

***Caution: Shorting High Voltage (greater than 3.3V or 5V depending on pin tolerance) to any Digital I/O bit will be likely to cause permanent board damage.***

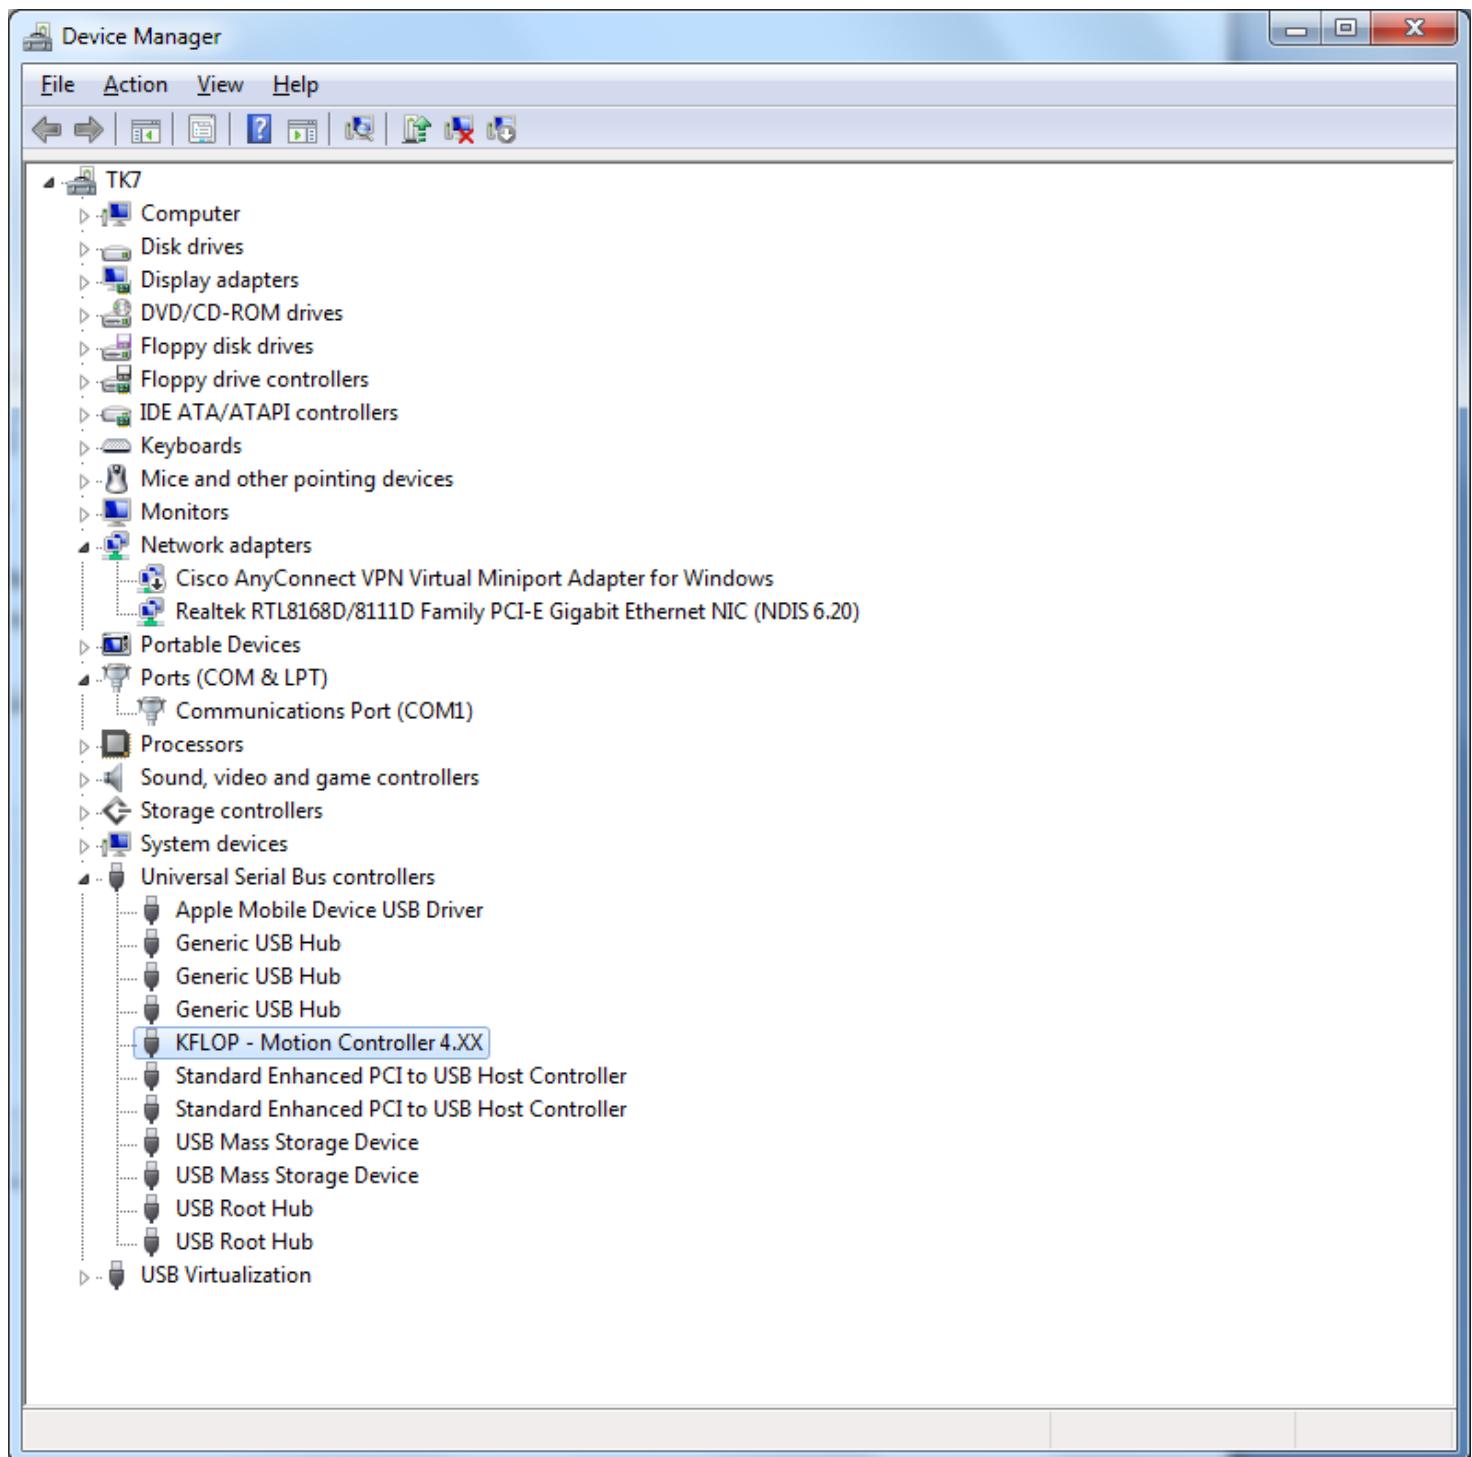

Digital I/O bits 46 and 47 are dedicated to the control of the two LED's on **KFLOP**. These two outputs are configured as outputs and tuned on when **KFLOP** powers up. They are available for use as User status if desired.

## KFLOP Functional Diagram

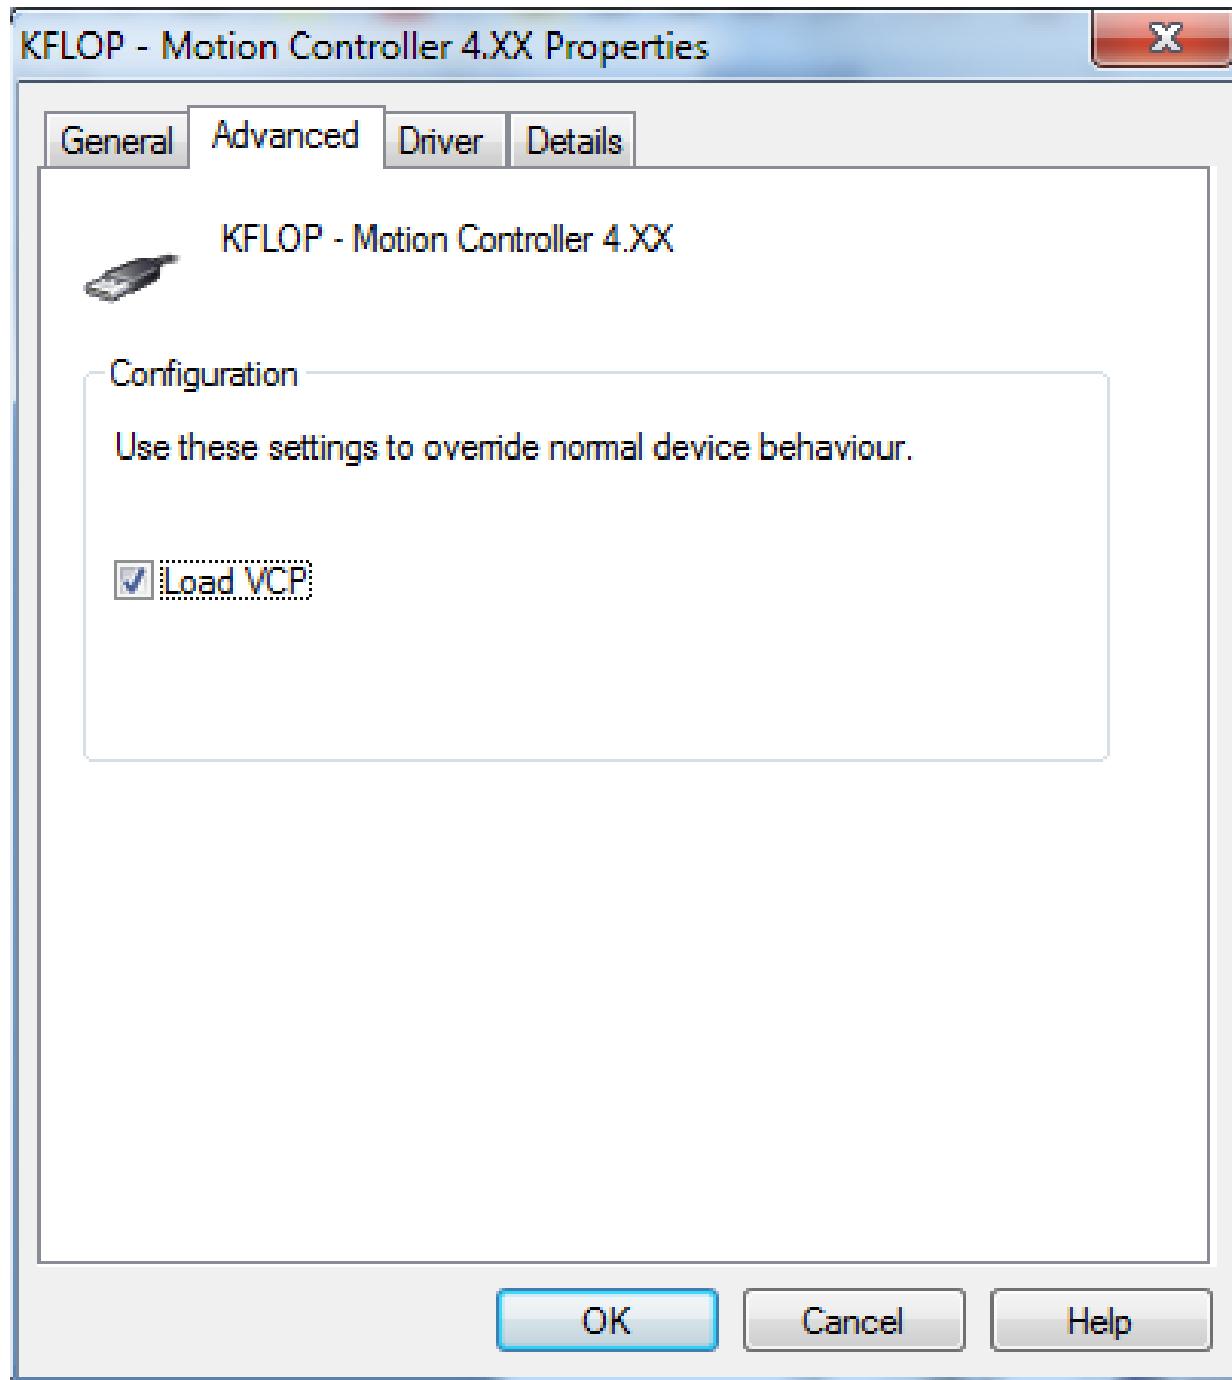

## Virtual COM Port Driver Installation

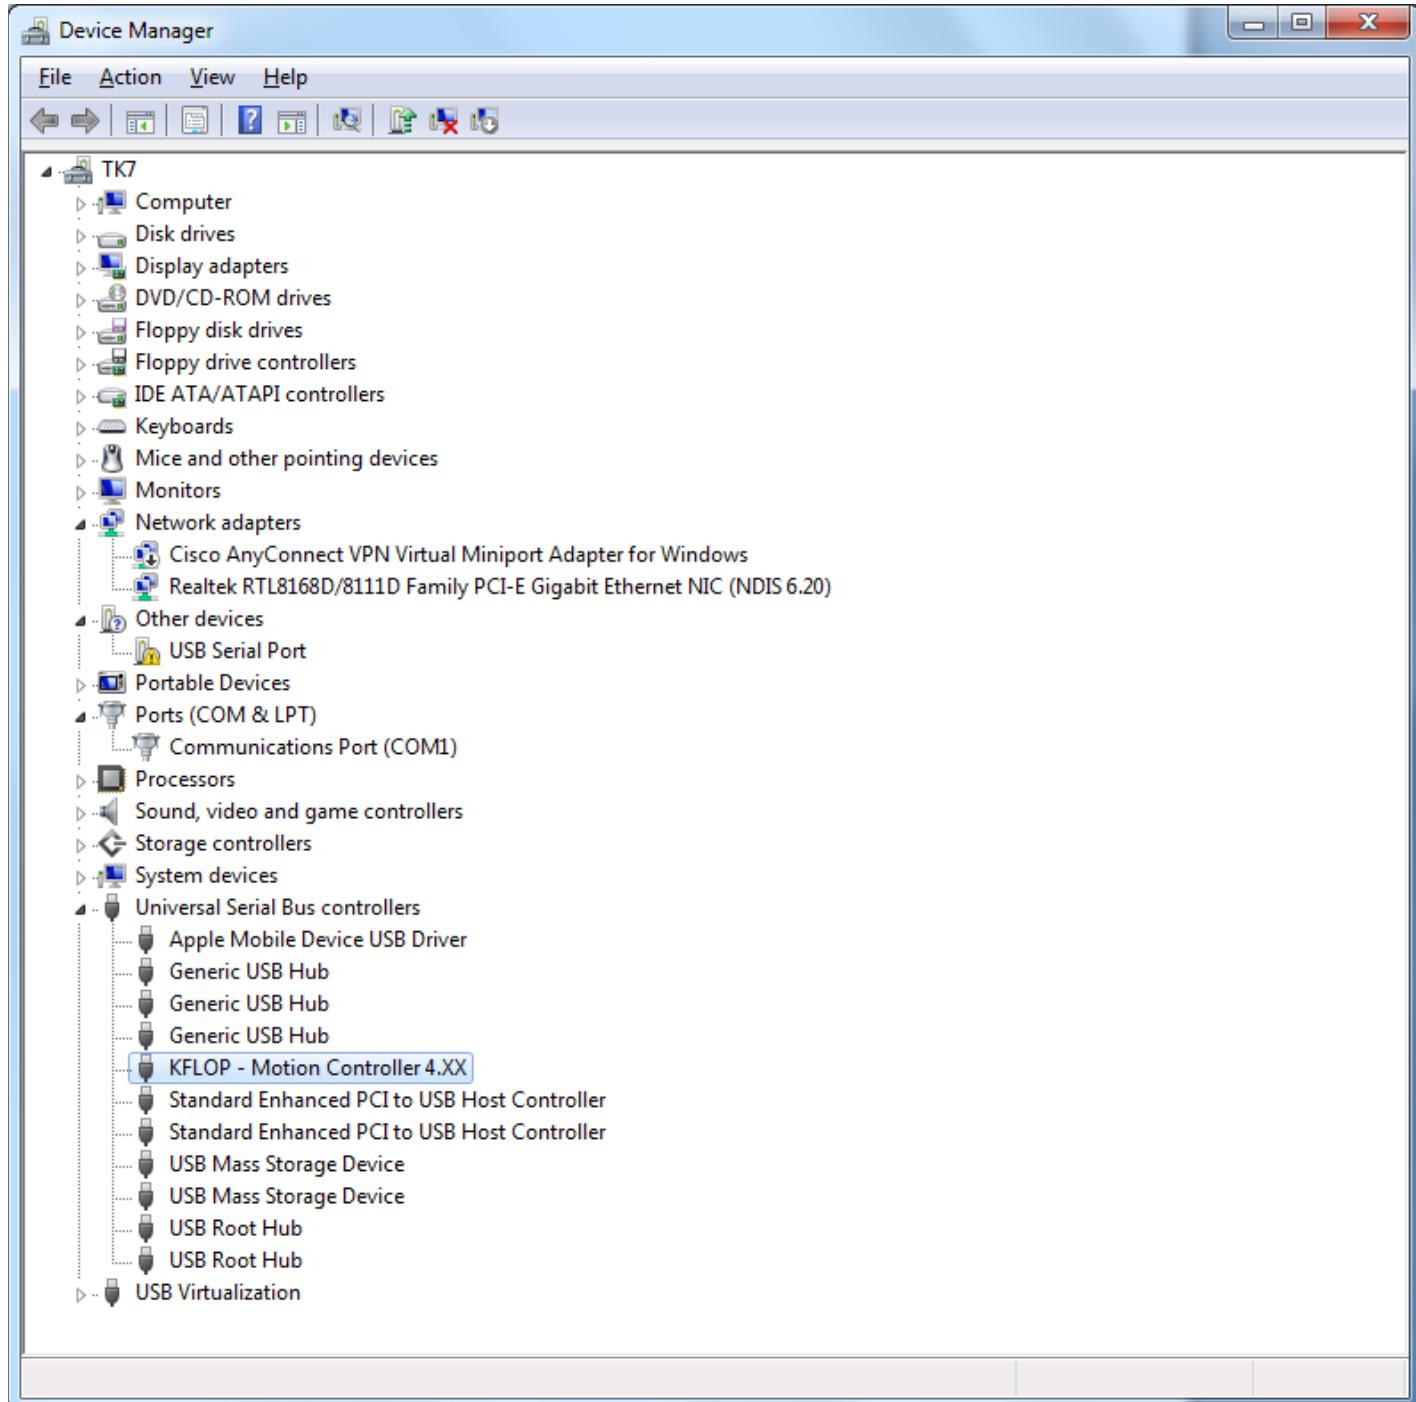

First install KFLOP normally using our USB Drivers. When successful there should be a KFLOP entry in Device manager as shown below

Now select “Properties” – “Advanced” – “Load VCP” (Virtual Com Port). Press OK.

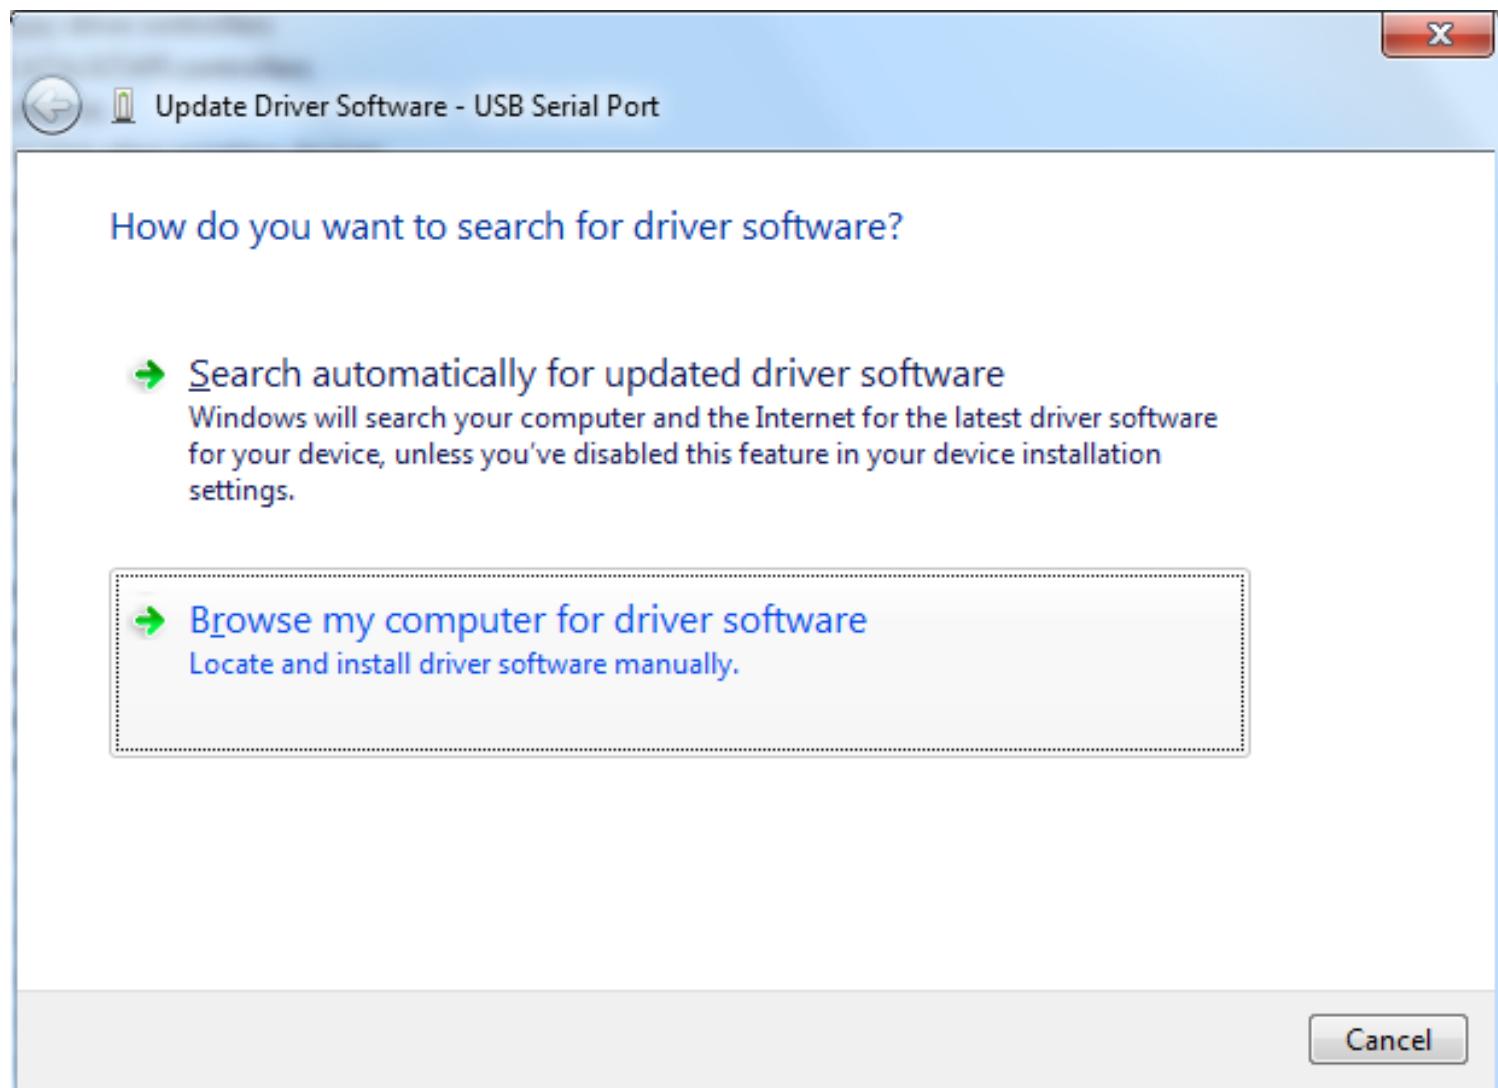

Then unplug/re-plug KFLOP. There should now be a USB Serial Port – but missing the driver

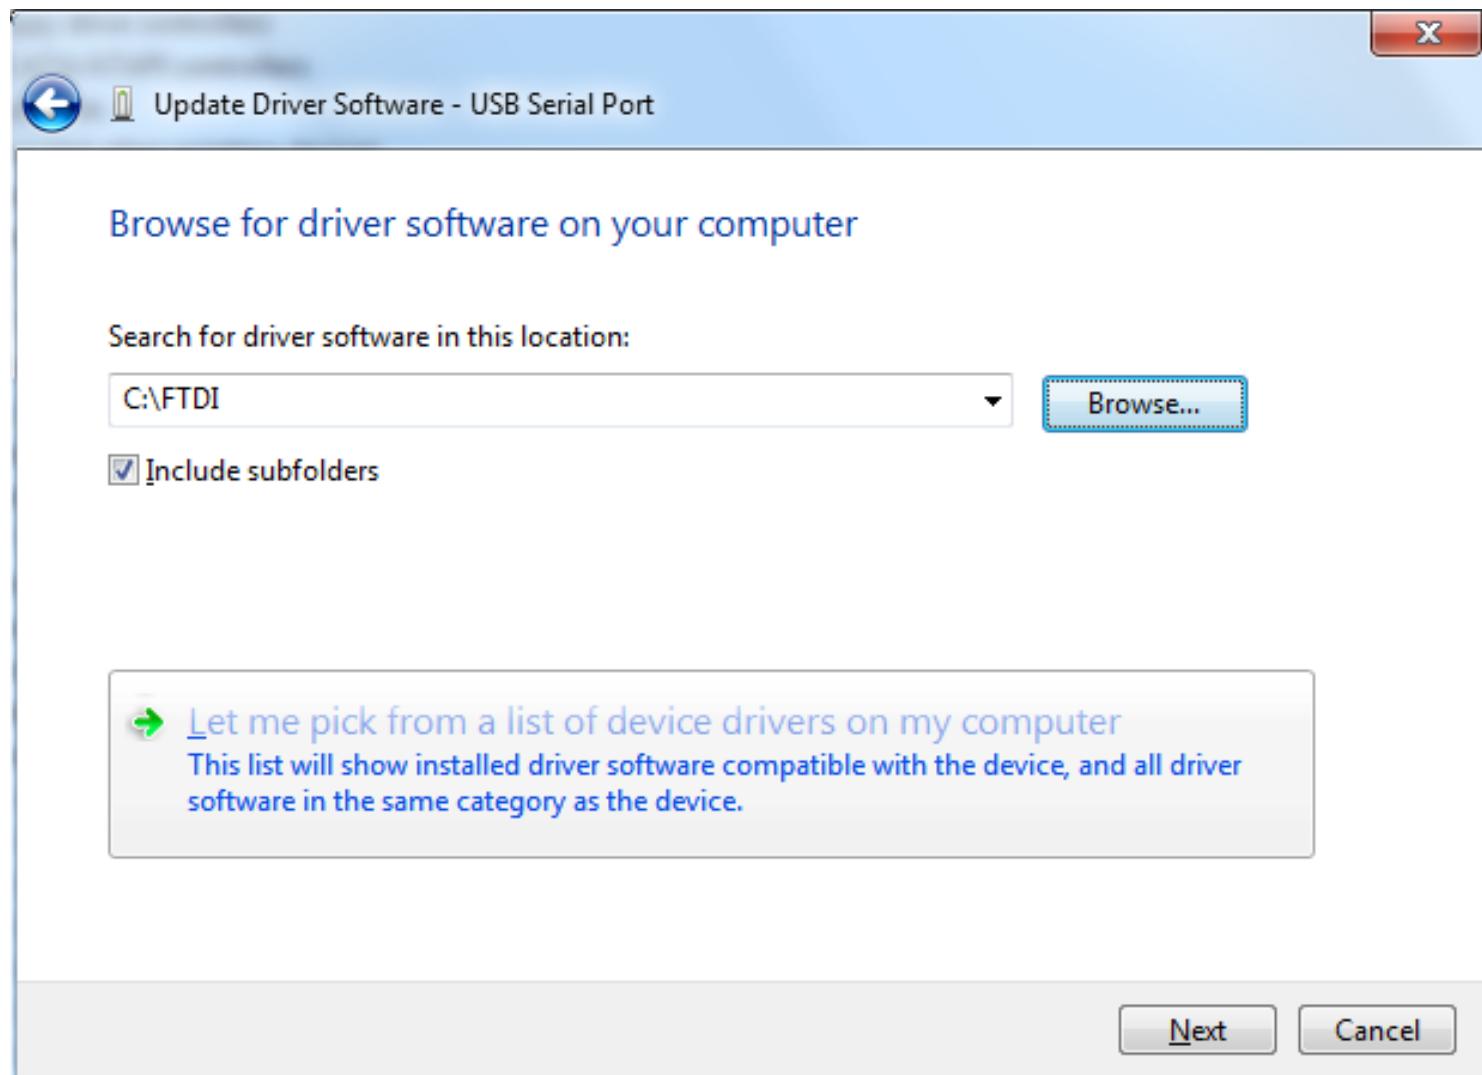

On USB Serial Port - right click – “Update Driver”

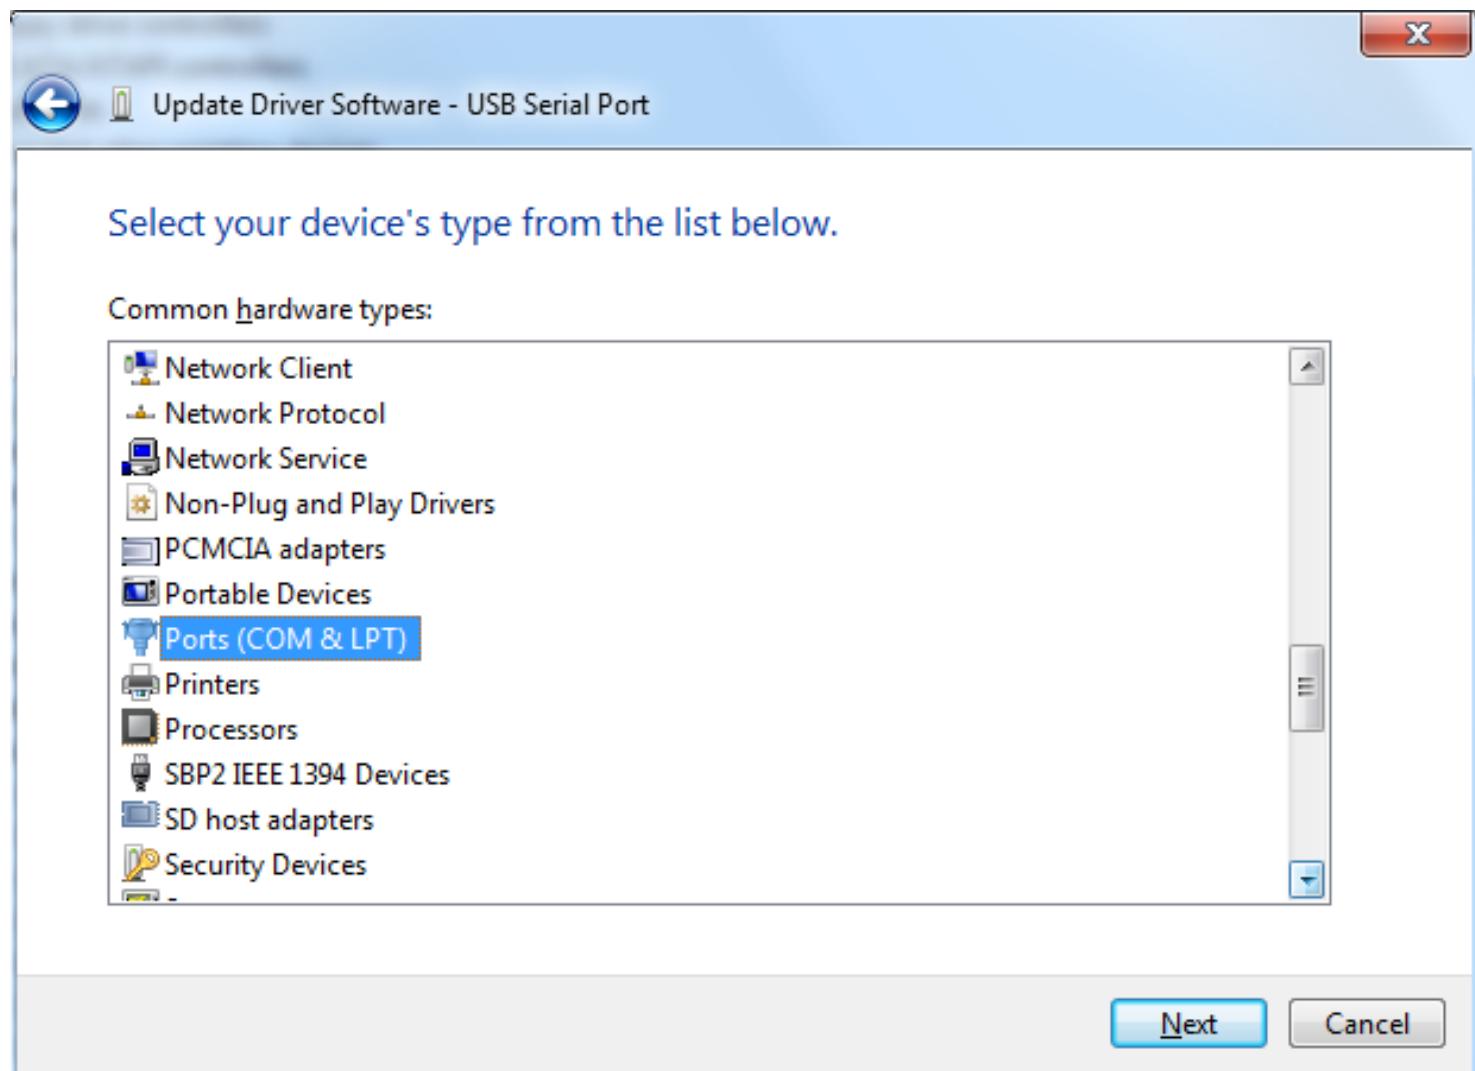

Select “Browse my computer”

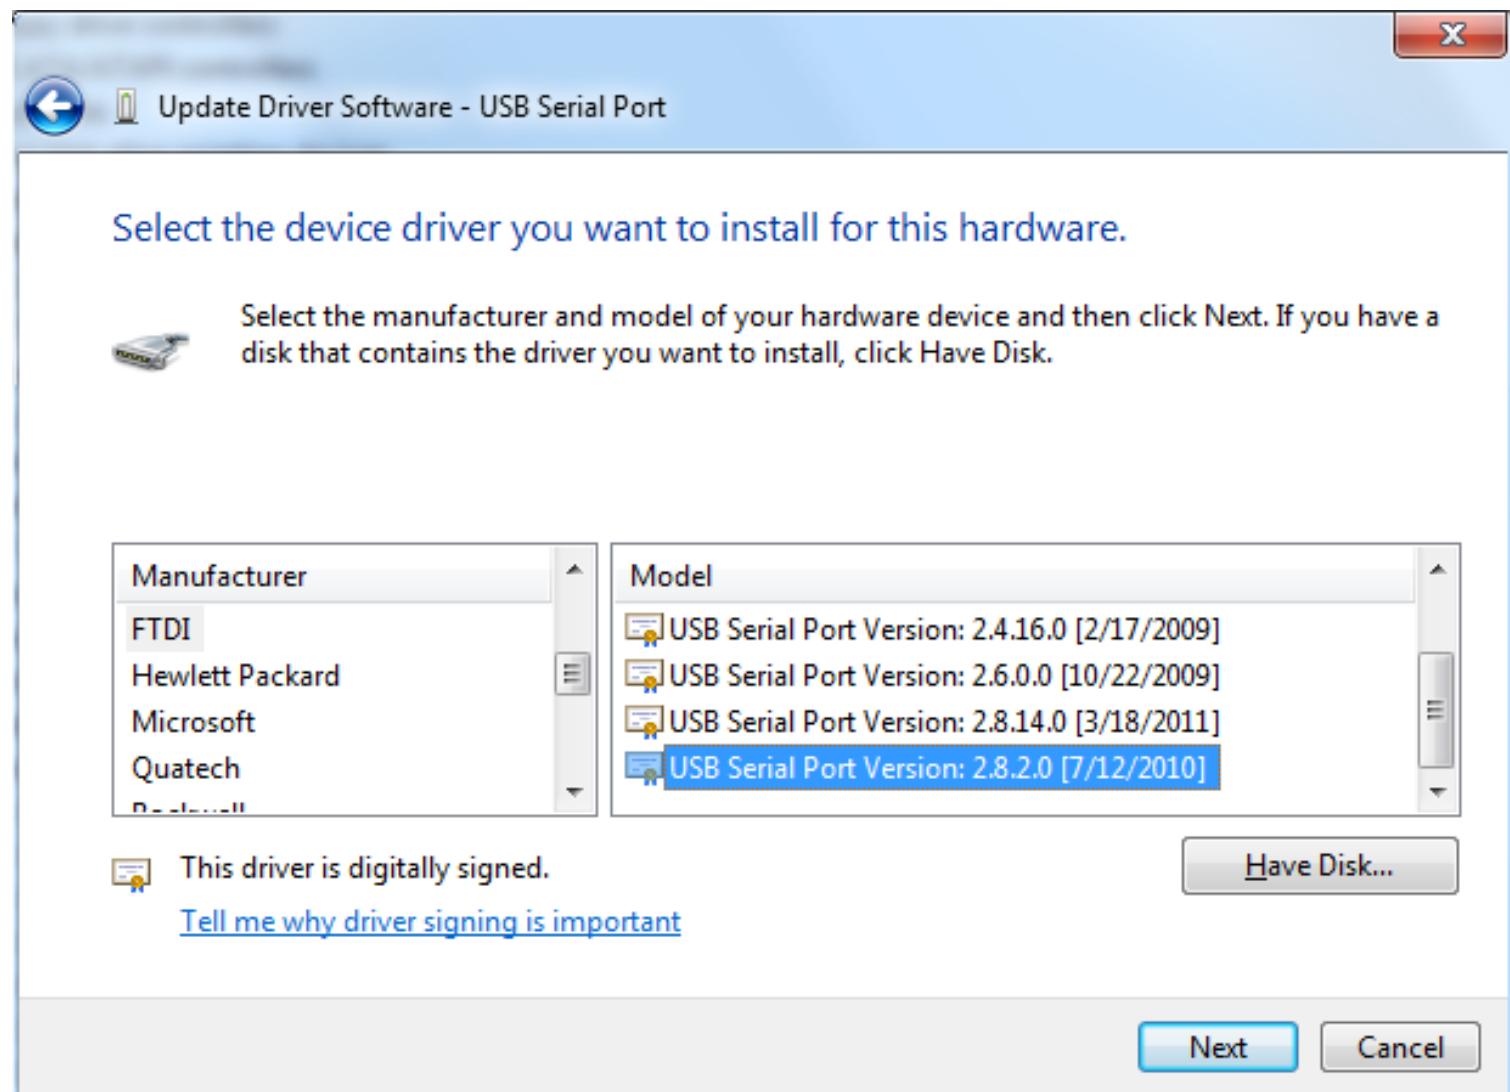

Then “Let me pick ...”

Select Device type as “**Ports**”

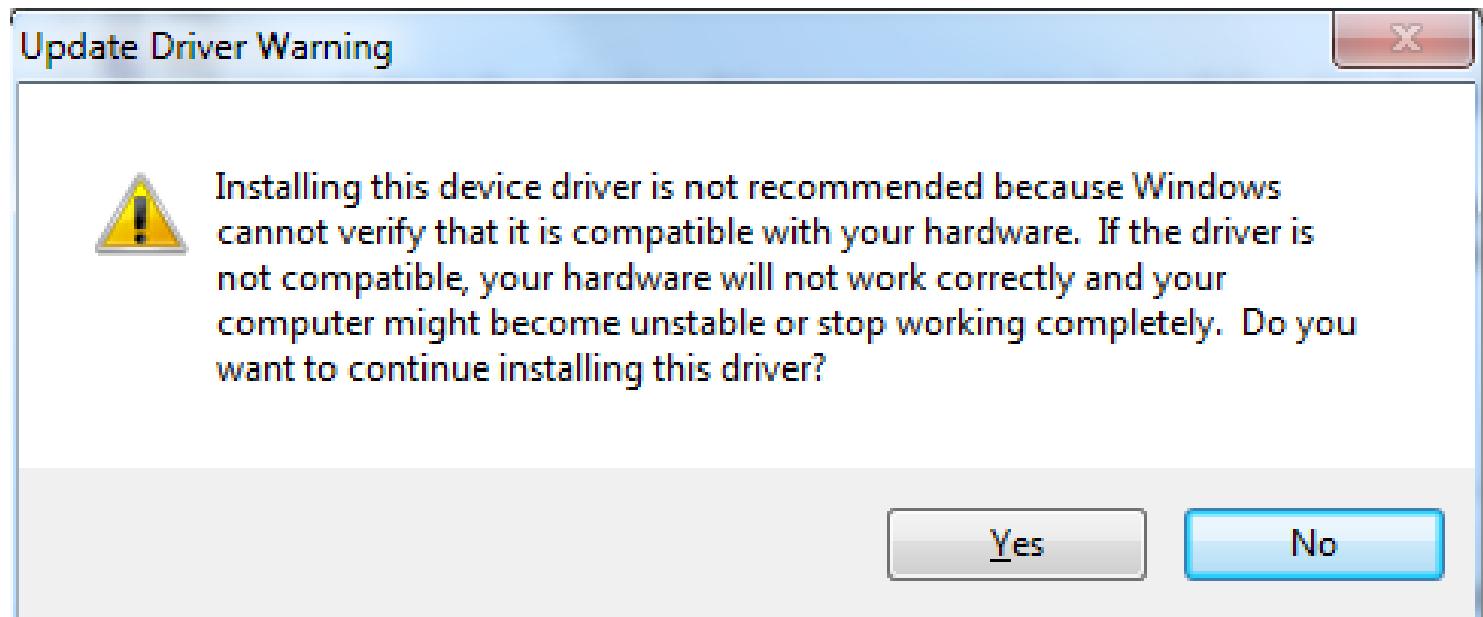

FTDI drivers should be pre-installed with Windows. Select FTDI and then latest USB Serial Port Version

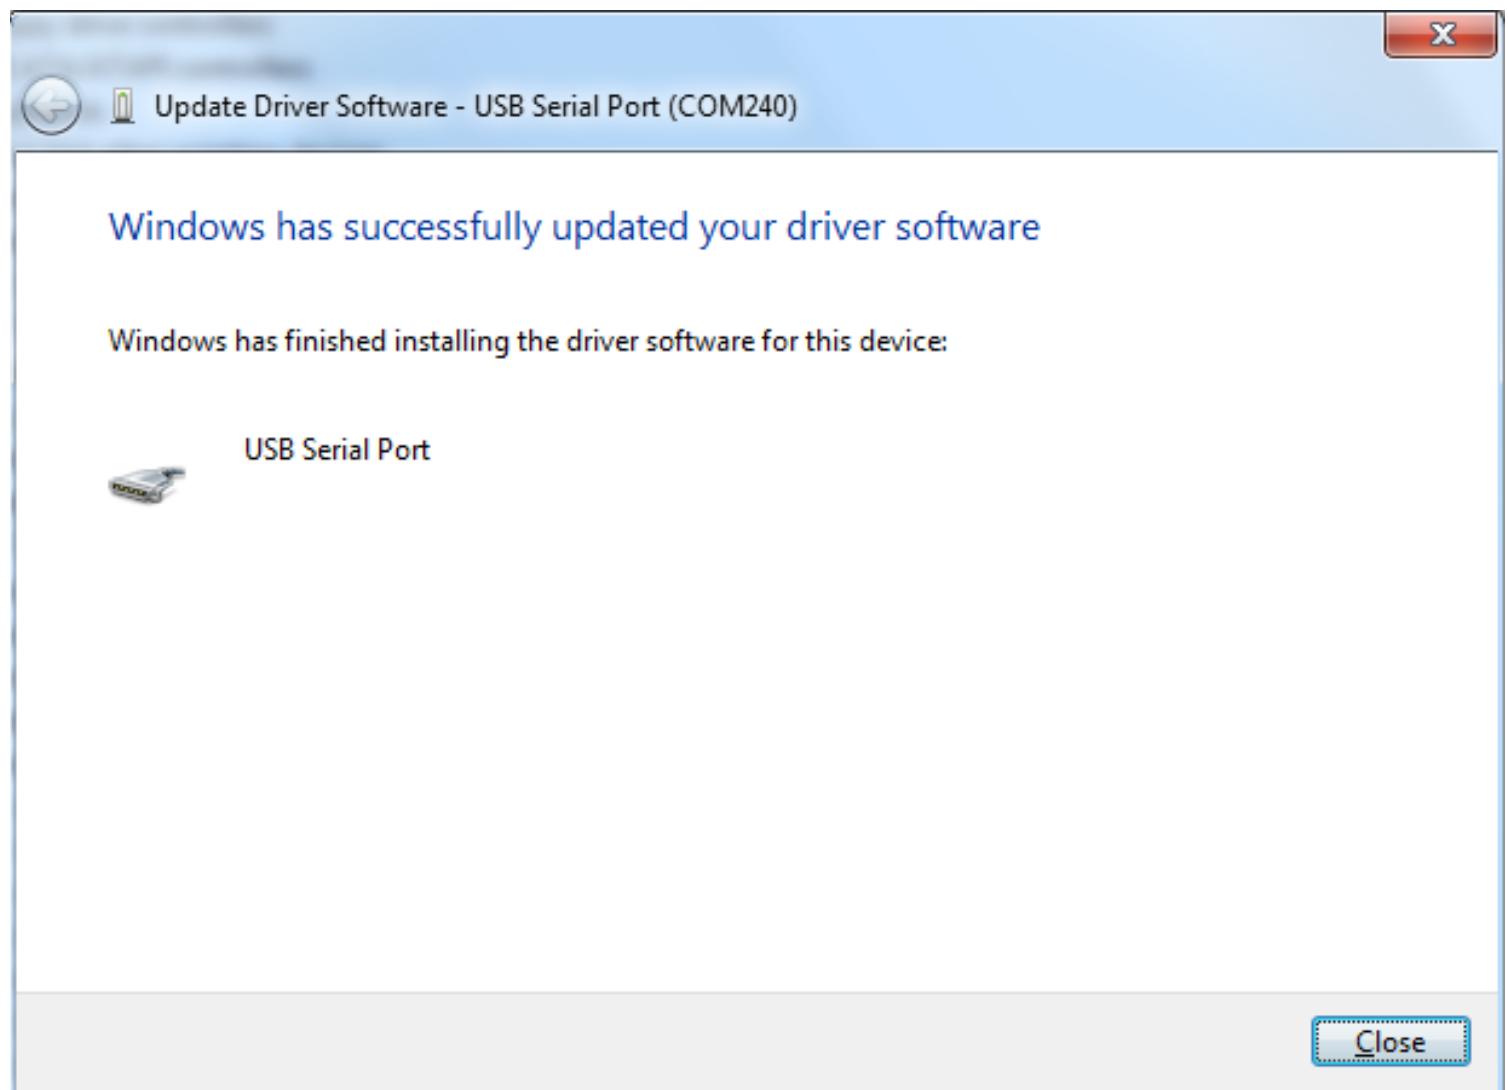

Manufacturer FTDI – USB Serial Port 2.8.2.0 (or other?)

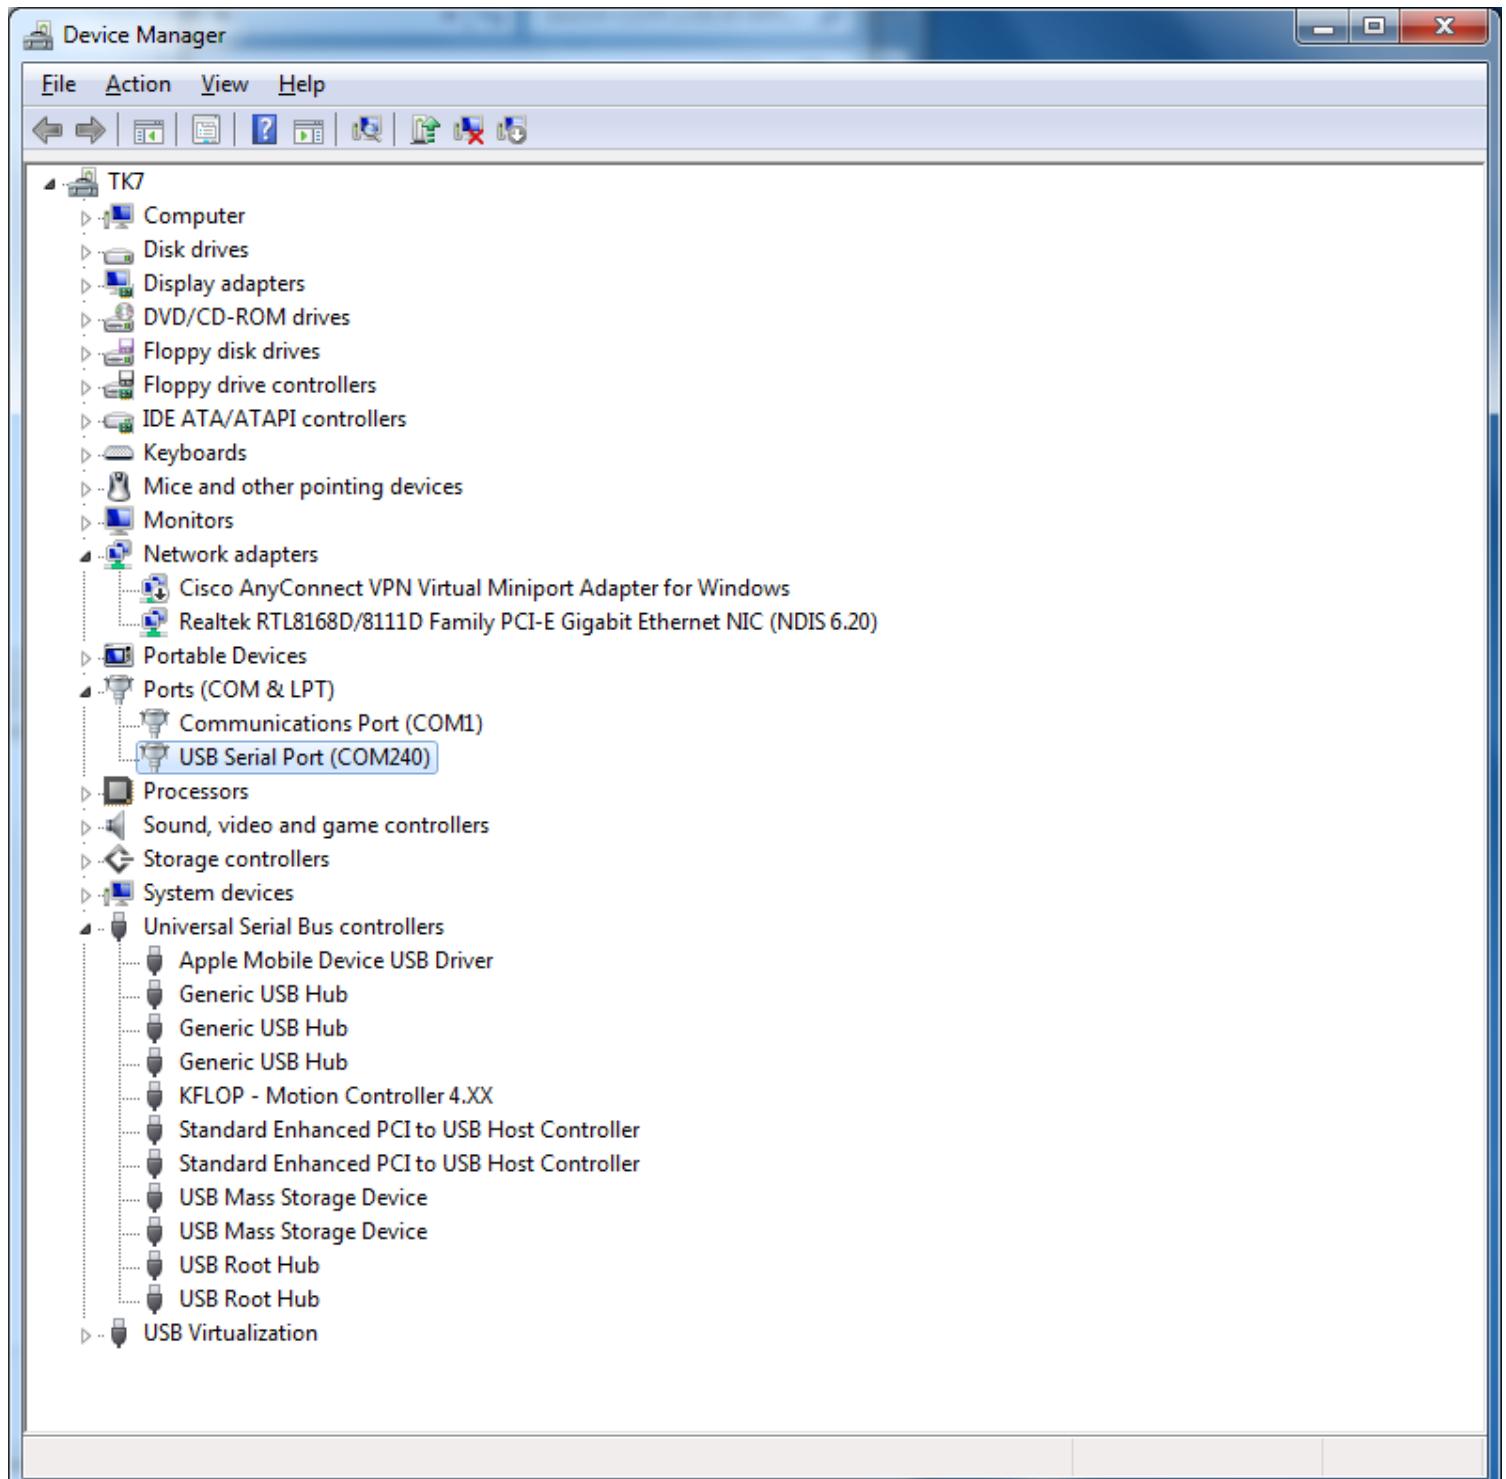

We have a different manufacturer ID so you get this warning – choose “Yes”

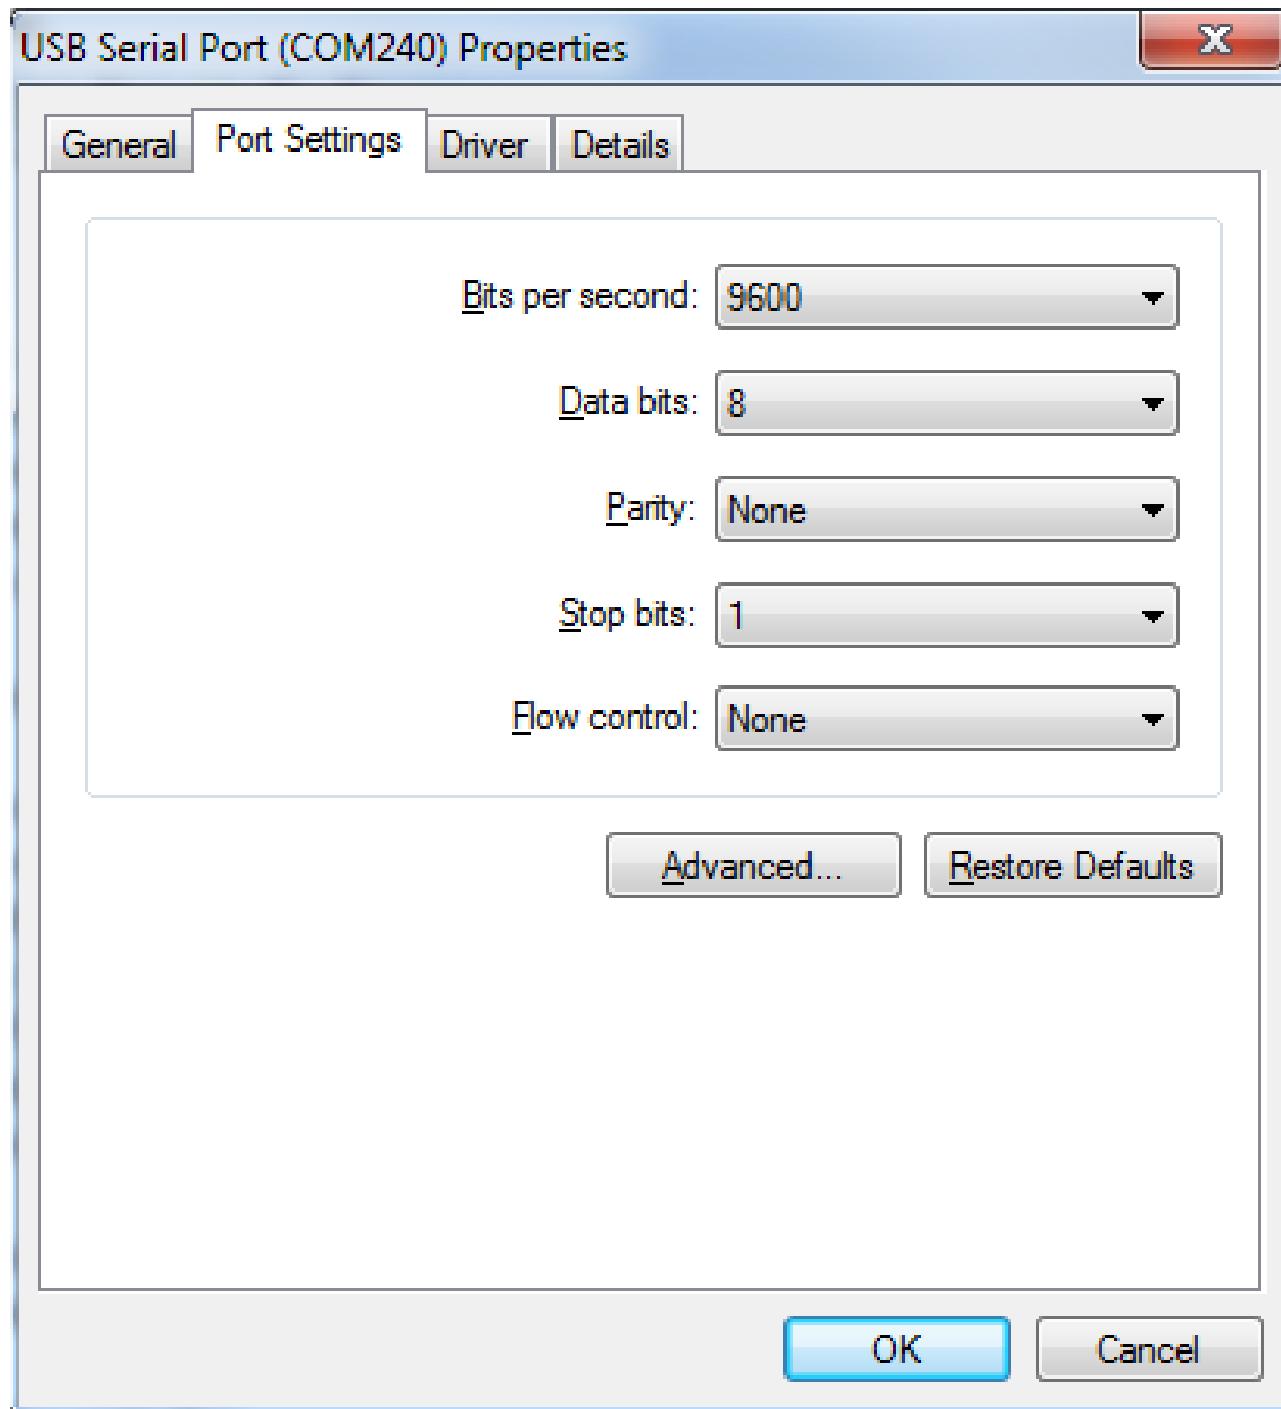

Installation should have been successful.

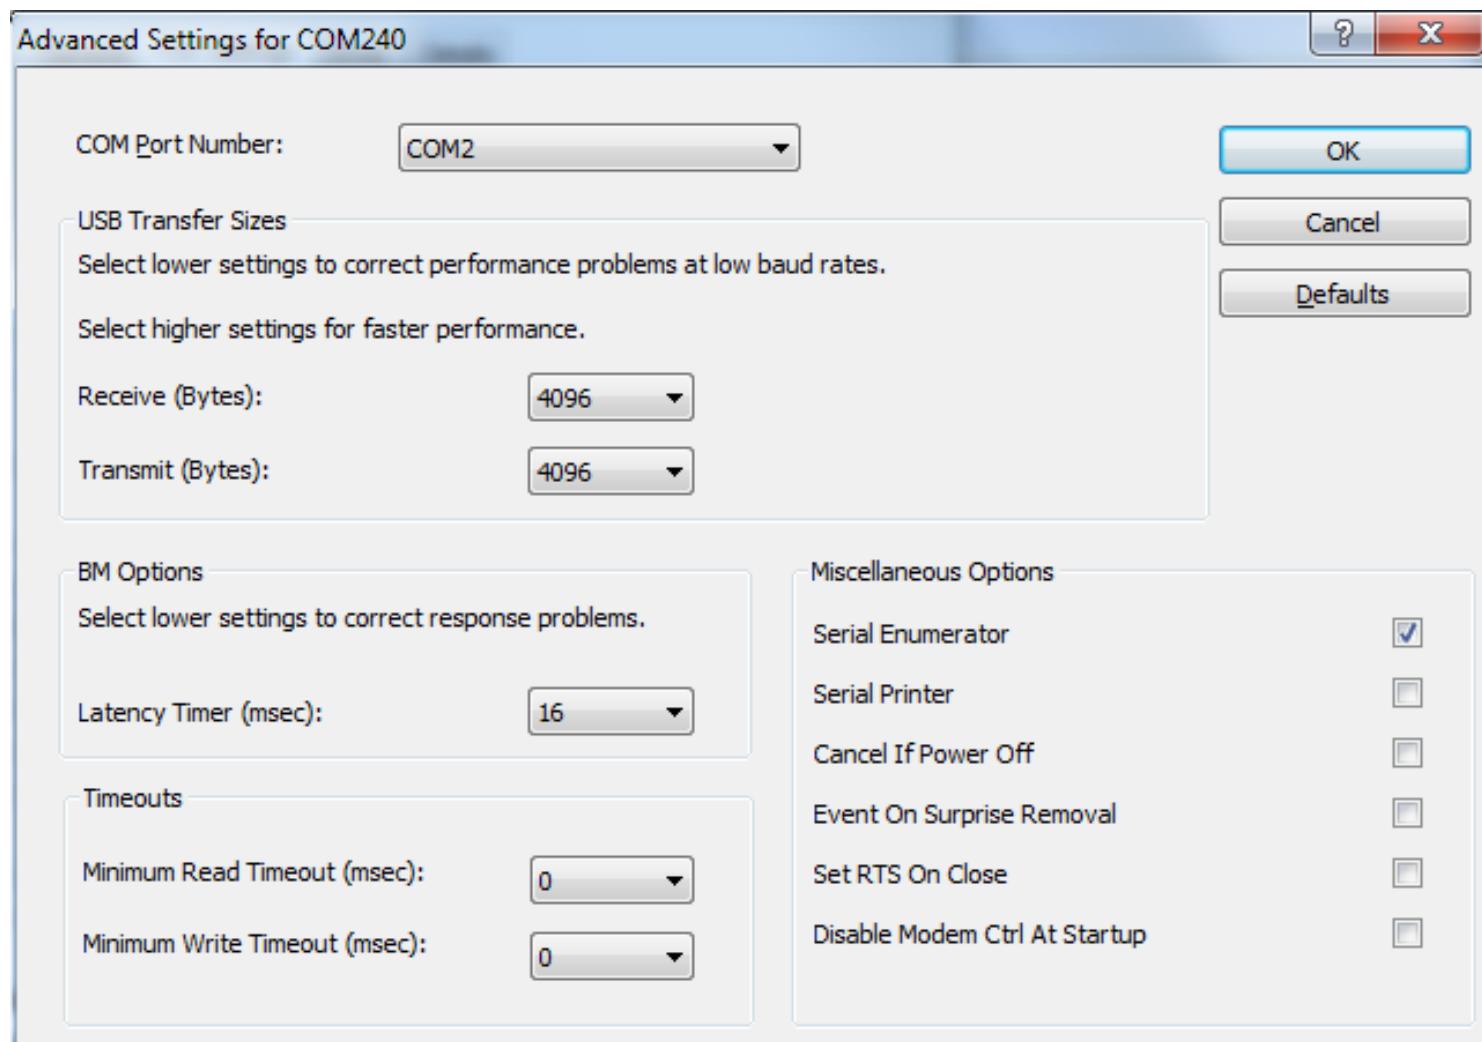

It should now work, but if you need to change the COM port number, do the following:

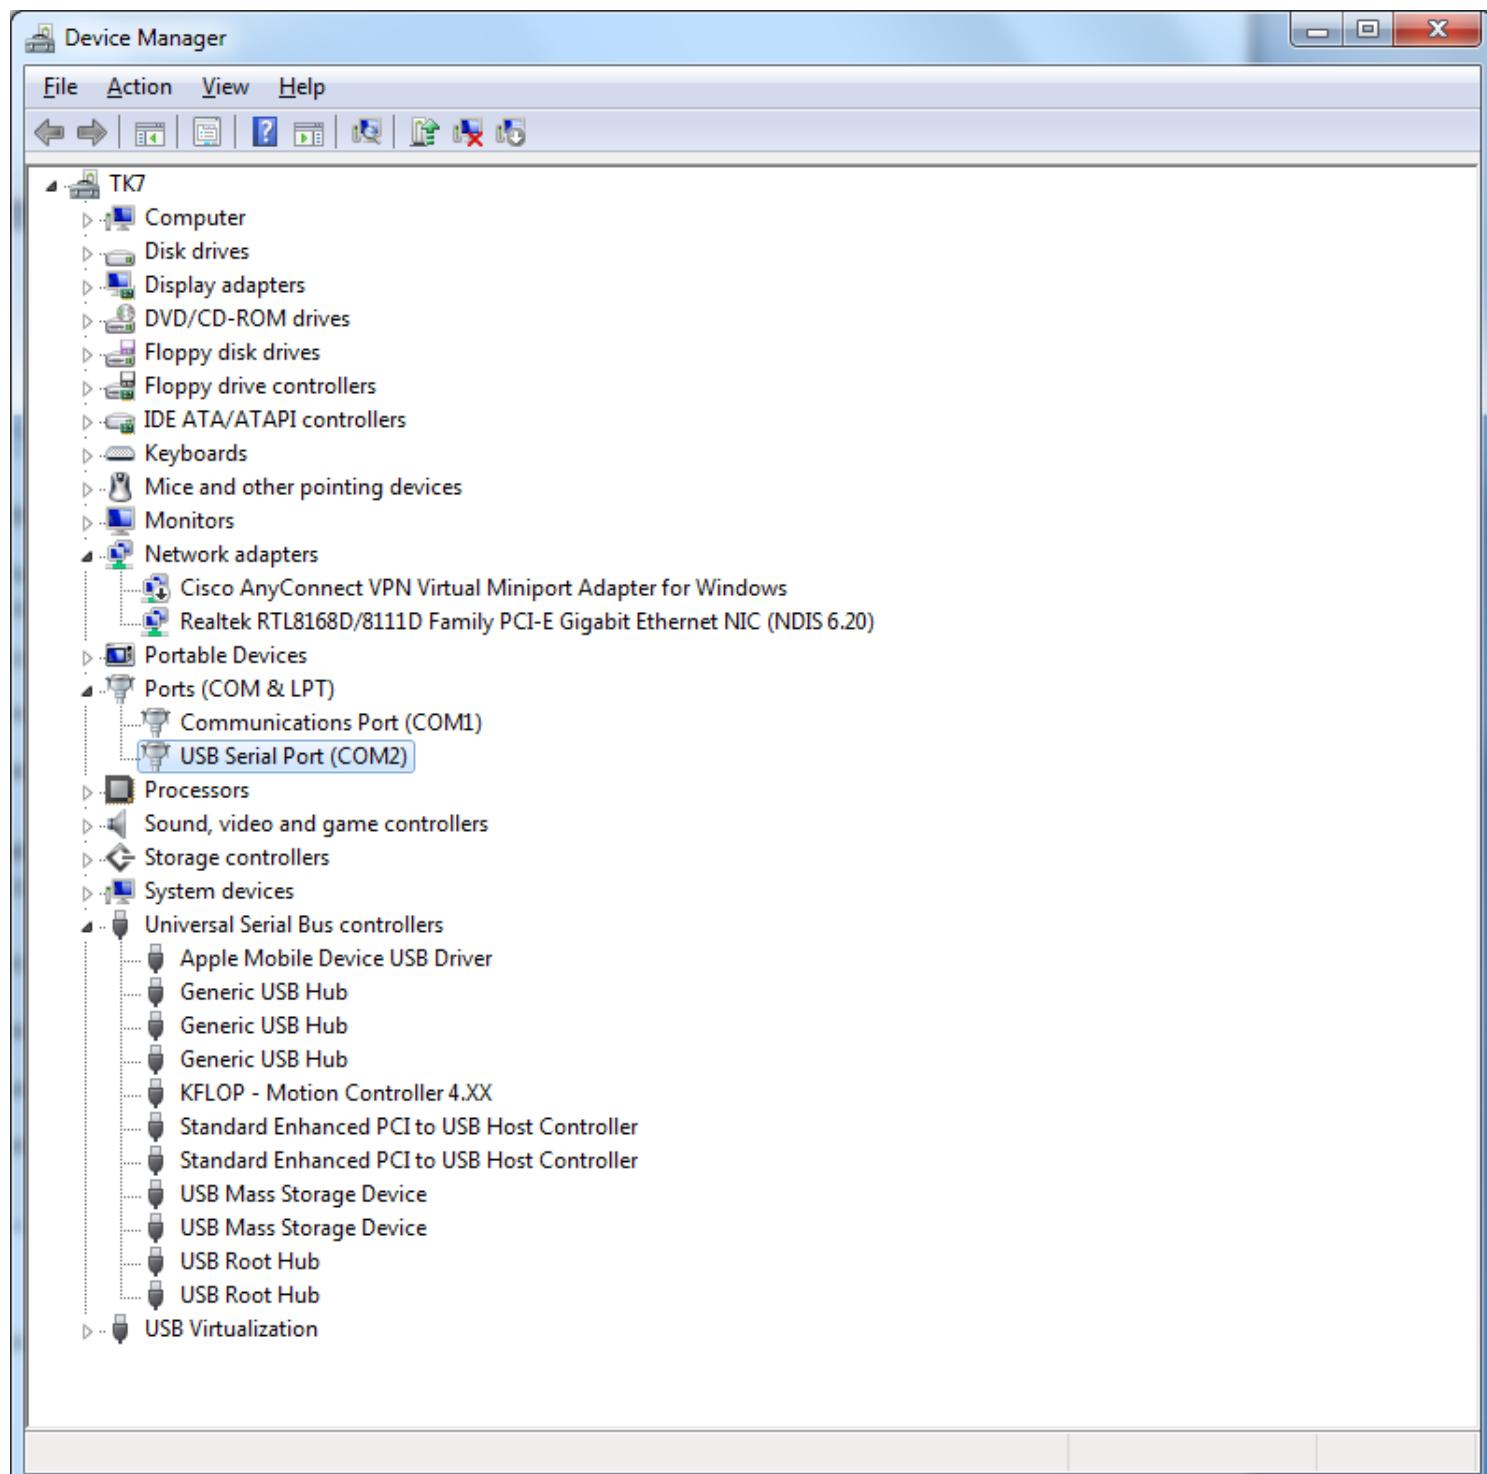

Right Click “Properties” – “Port Settings”

**Select "Advanced"**

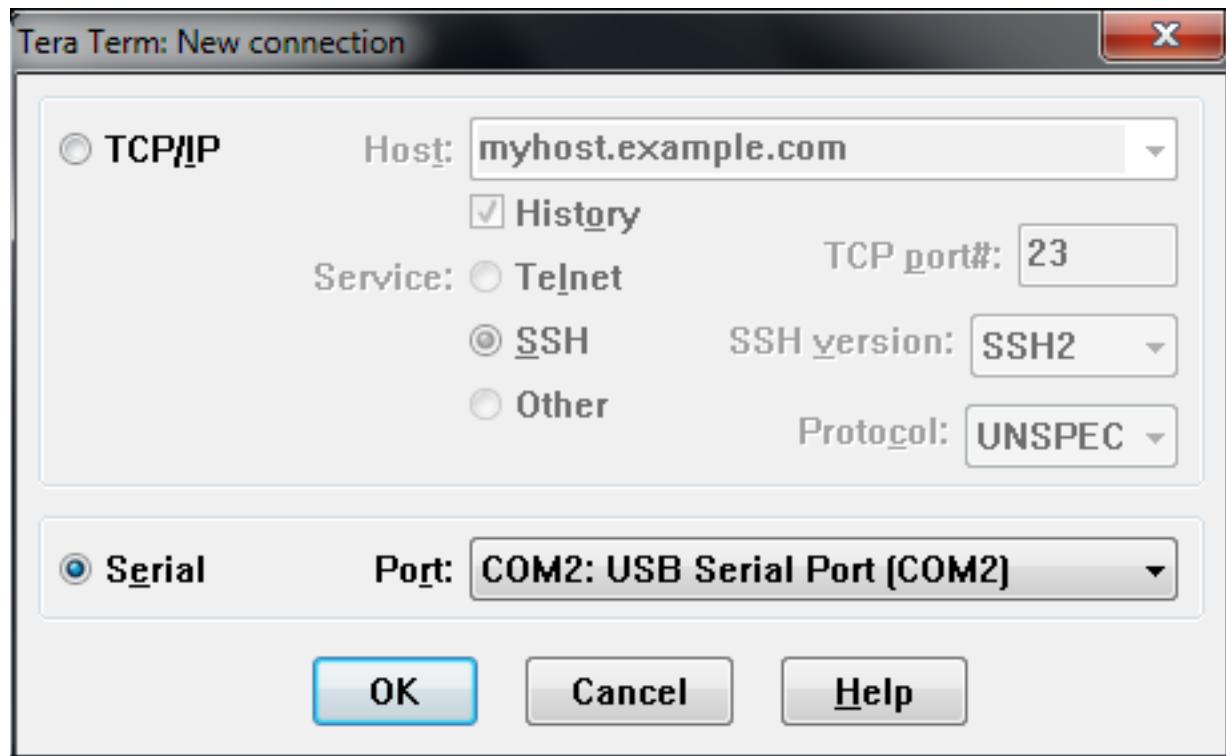

Change to other COM port if necessary (COM2)

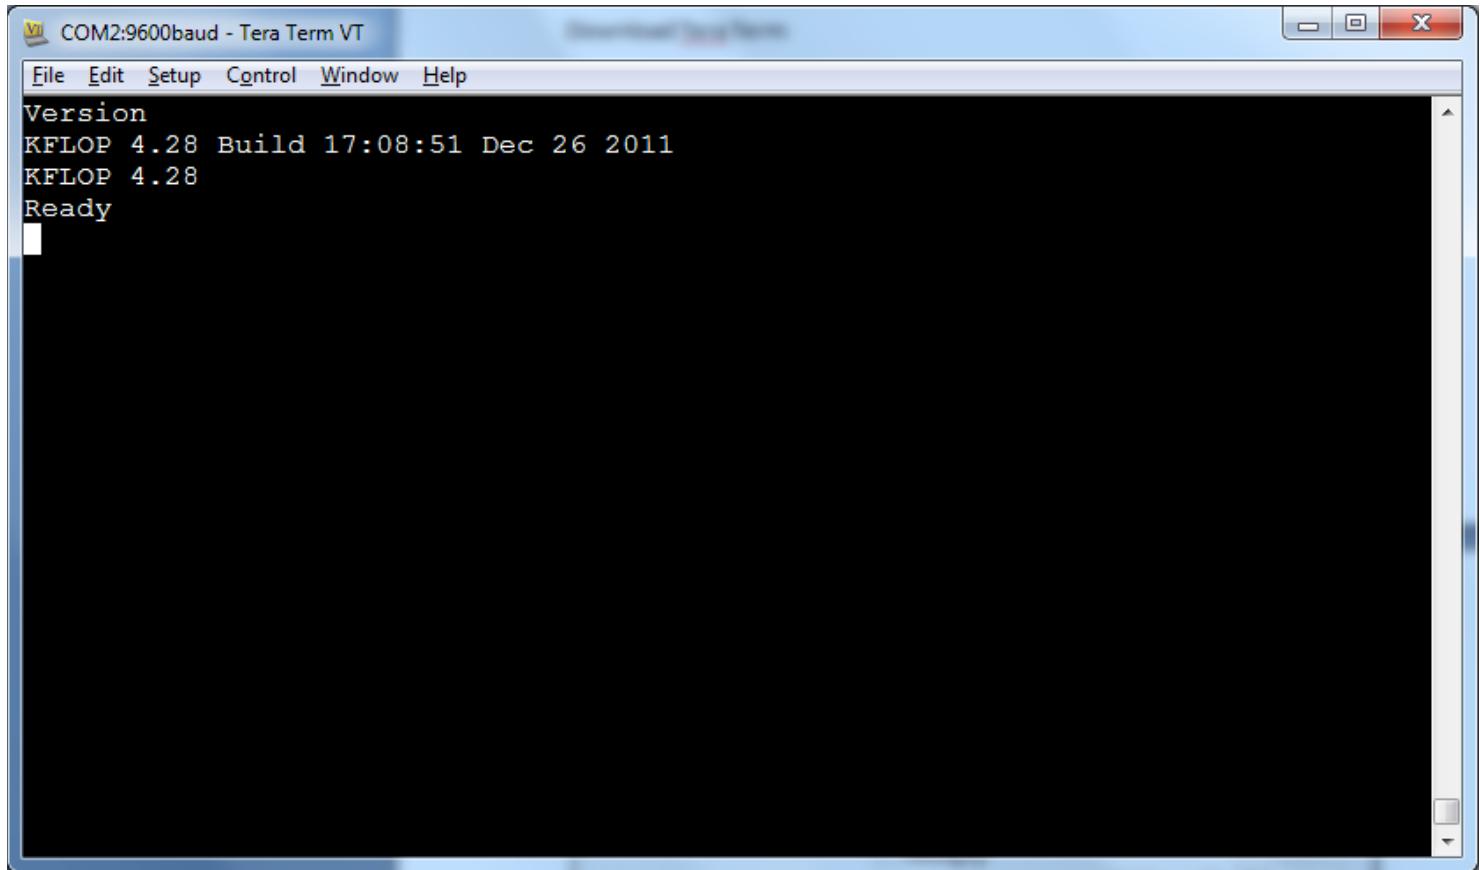

To test download and install a serial com program like Tera Term from:

<http://ttssh2.sourceforge.jp>

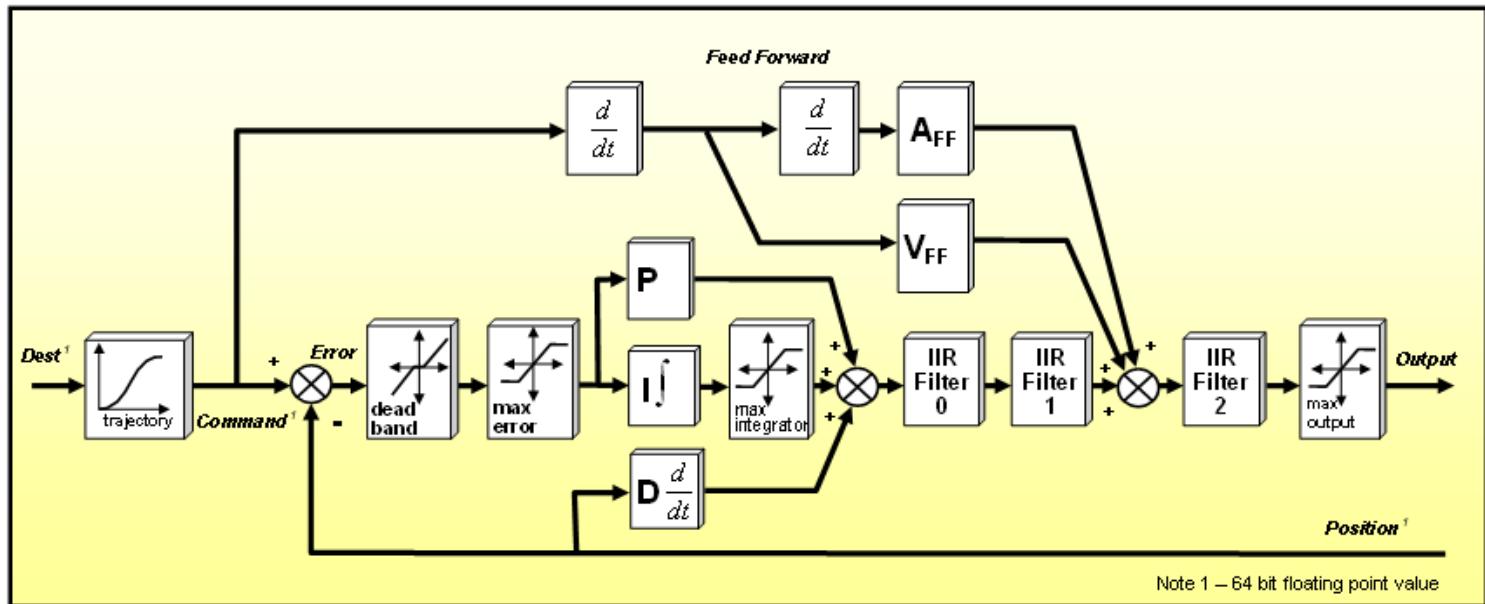

Run it and select “Serial” and the Com port you defined

Type “**Version**” and KFLOP should respond

### KMotionDLL

---

```
CKMotionDLL(int board);
```

Creates a CKMotionDLL object to be used to communicate to a specific board.

*board*

specifies which board in the system the object is associated with

---

```
int WriteLine(const char *s);
```

Writes a null terminated string of characters to a specified **KMotion** Board.  
There is no wait for any response.

#### Return Value

0 if successful, non-zero if unsuccessful (invalid board specified)

#### Parameters

*s*

Null terminated string to send

#### Example

```
#include "KMotionDLL.h"
CKMotionDLL KM;
if (KM.WriteLine(0, "Move0=1000") MyError();
```

---

```
int WriteLineReadLine(const char *s, char *response);
```

Writes a null terminated string of characters to a specified **KMotion** Board.  
Waits for a response string. This command is thread safe. It waits for the token for the specified board, sends the command, waits for the response,

then releases the board.

### Return Value

0 if successful, non-zero if unsuccessful (invalid board specified, timeout on the response)

### Parameters

*s*

Null terminated string to send

*response*

Buffer to receive the null terminated string received as response

### Example

```
#include "KMotionDLL.h"
CKMotionDLL KM;
char resp[256];
while
{
    if (KM.WriteLineReadLine(0, "CheckDone0", resp)
MyError();
    if (strcmp(resp, "1") == 0) break;
}

---

int ReadLineTimeOut(char *buf, int TimeOutms);
```

Waits for a response string from a previously issued command. Note in a multi-process or multi thread environment the **KMotion** board should be locked prior to issuing a command that has a response(s). Otherwise there is a possibility that another process or thread may receive the expected response.

### Return Value

0 if successful, non-zero if unsuccessful (invalid board specified, timeout on the response)

## Parameters

*buf*

Buffer to receive the Null terminated string received as response

*TimeOutms*

Amount of time to receive a response

## Example

```
#include "KMotionDLL.h"
CKMotionDLL KM(0);
char resp1[256];
char resp2[256];
char resp3[256];

// first get the token for the board to allow uninterrupted access
if (KM.WaitToken() != KMOTION_LOCKED) MyError();

// tell the board to send 24 (32 bit) words at offset 0
if (KM.WriteLine("GetGatherHex 0 24")) MyError();

// receive the data (8 hex words per line)
if (KM.ReadLineTimeout(resp1)) MyError();
if (KM.ReadLineTimeout(resp2)) MyError();
if (KM.ReadLineTimeout(resp3)) MyError();

// release our access to the board

KM.ReleaseToken();
```

---

**int WaitToken();**

Waits until the token for the specified **KMotion** board can be obtained. Call this function whenever uninterrupted access to a **KMotion** board is required. For example before a command where several lines of response will be returned. Release the token as quickly as possible by calling the [ReleaseToken](#) function as all other access to the locked board will be blocked until released.

**Return Value**

0 if successful, non-zero if unsuccessful (invalid board specified)

**Parameters**

none

**Example**

```
#include "KMotionDLL.h"
CKMotionDLL KM(0);
char resp1[256];
char resp2[256];
char resp3[256];

// first get the token for the board to allow uninterrupted access
if (KM.WaitToken() != KMOTION_LOCKED) MyError();

// tell the board to send 24 (32 bit ) words at offset 0
if (KM.WriteLine("GetGatherHex 0 24")) MyError();

// receive the data (8 hex words per line)
if (KM.ReadLineTimeout(resp1)) MyError();
if (KM.ReadLineTimeout(resp2)) MyError();
if (KM.ReadLineTimeout(resp3)) MyError();

// release our access to the board

KM.ReleaseToken();
```

---

```
int KMotionLock();
```

Attempts to obtain the token of the specified **KMotion** board.. Call this function whenever uninterrupted access to a **KMotion** board is required. For example before a command where several lines of response will be returned. Release the token as quickly as possible by calling the [ReleaseToken](#) function as all other access to the locked board will be blocked until released. This function is similar to the [WaitToken](#) function, except that it returns immediately (instead of waiting) if the board is already locked.

## Return Value

KMOTION\_LOCKED=0, // (and token is locked) if KMotion is available for use

KMOTION\_IN\_USE=1 // if already in use

KMOTION\_NOT\_CONNECTED=2 // if error or not able to connect

## Parameters

none

## Example

```
#include "KMotionDLL.h"
CKMotionDLL KM(0);
char resp1[256];
char resp2[256];
char resp3[256];
int result;

// first get the token for the board to allow uninterrupted access
do
{
    result = KM.KMotionLock();
    if (result == KMOTION_NOT_CONNECTED) MyError();
    if (result == KMOTION_IN_USE) DoOtherProcessing();
} while( result != KMOTION_LOCKED)

// tell the board to send 24 (32 bit) words at offset 0
if (KM.WriteLine("GetGatherHex 0 24")) MyError();

// receive the data (8 hex words per line)
if (KM.ReadLineTimeout(resp1)) MyError();
if (KM.ReadLineTimeout(resp2)) MyError();
if (KM.ReadLineTimeout(resp3)) MyError();

// release our access to the board

KM.ReleaseToken();
```

---

```
void ReleaseToken();
```

Releases the previously obtained token of the specified **KMotion** board. See [WaitToken](#) and [LockKMotion](#) functions. The token should always be released as quickly as possible as all other access to the locked board will be blocked until released.

### Return Value

none - the function cannot fail

### Parameters

none

specifies which board in the system the command applies to

### Example

```
#include "KMotionDLL.h"
CKMotionDLL KM(0);
char resp1[256];
char resp2[256];
char resp3[256];
int result;

// first get the token for the board to allow uninterrupted access
do
{
    result = KM.KMotionLock();
    if (result == KMOTION_NOT_CONNECTED) MyError();
    if (result == KMOTION_IN_USE) DoOtherProcessing();
} while(result != KMOTION_LOCKED)

// tell the board to send 24 (32 bit) words at offset 0
if (KM.WriteLine("GetGatherHex 0 24")) MyError();

// receive the data (8 hex words per line)
if (KM.ReadLineTimeout(resp1)) MyError();
if (KM.ReadLineTimeout(resp2)) MyError();
if (KM.ReadLineTimeout(resp3)) MyError();
```

```
// release our access to the board
KM.ReleaseToken();

---

int Failed();
```

This function should be called whenever an error is detected with a **KMotion** board. This function disconnects the driver, flags the board as disconnected, and displays the error message shown below. A user program may typically detect a timeout error or invalid data error if the **KMotion** board is powered down or unplugged while communication is in progress. Calling this function will force any subsequent attempts to access the board to wait for a board to be connected, re-connect, flush any buffers, etc...

"Read Failed - Auto Disconnect"

### **Return Value**

always 0 - the function cannot fail

### **Parameters**

none

### **Example**

```
#include "KMotionDLL.h"
CKMotionDLL KM(0);

if (KM.KMotionLock() == KMOTION_LOCKED) // see if we can get access
{
    // upload bulk status

    if (UploadStatus())
    {
        // error reading status
        KM.Failed();
    }
    KM.ReleaseToken();
}
```

---

```
int LoadCoff(int Thread, const char *Name, bool
```

```
PackToFlash);
```

This function downloads a compiled C program to the memory of the specified **KMotion** board.

C Programs that run in the **KMotion** Board are normally compiled using the included and integrated compiler in the **KMotion** Application. Using the **KMotion** Application the user's C Program should be loaded into a selected thread and compiled. This will automatically generate a COFF executable with the same name and in the same directory as the C Source code, but with a .out extension. It is the users responsibility to keep track of which thread the COFF executable was compiled to execute in.

The downloaded code may then be executed by issuing the "Execute" command

### Return Value

returns 0 - if successful

### Parameters

*Thread*

KMotion Thread that the program should be loaded into

*Name*

Filename of coff file to download

*PackToFlash*

Internal system command always specify as false

### Example

```
#include "KMotionDLL.h"
CKMotionDLL KM(0);
unsigned int EntryPoint;
```

```

if (KM.LoadCoff(1, "C:\\test.out", false)) return 1;

KM.WriteLine("Execute 0");

---

int ServiceConsole();

```

Services the **KMotion** Console data stream. The Console is a place where all unsolicited data, such as errors, or data "Printed" by user programs goes to. In between processing commands, **KMotion** uploads any unsolicited data it may have up to the host. The KMotionDLL driver buffers this data until some process declares itself as a *Console Handler* (See **SetConsoleCallback**) and makes calls to this function *ServiceConsole*.

This function should be called at regular intervals. If console data is available a call back to the Console Handler will occur with one line of data.

### **Return Value**

returns 0 - if successful

### **Parameters**

*none*

### **Example**

```

#include "KMotionDLL.h"
CKMotionDLL KM(0);

int ConsoleHandler(const char *buf)
{
    MyLogData(buf);
    return 0;
}

KM.SetConsoleCallback(ConsoleHandler);
KM.ServiceConsole();

```

---

```
int SetConsoleCallback(CONSOLE_HANDLER *ch);
```

Sets the user provided console callback function.

**Return Value**

returns 0 - if successful

**Parameters**

*ch*

name of console handler function

**Example**

```
#include "KMotionDLL.h"
CKMotionDLL KM(0);
int ConsoleHandler(const char *buf)
{
    MyLogData(buf);
    return 0;
}

.

.

.

KM.SetConsoleCallback(ConsoleHandler);
KM.ServiceConsole();
```

---

```
int CompileAndLoadCoff(const char *Name, int Thread);
or
int CompileAndLoadCoff(const char *Name, int Thread,
char *Err, int MaxErrLen);
```

Compiles the specified [C Program](#) file, downloads the object code to the specified Thread space, and sets the Entry Point, for the specified thread. Two versions of the function are supplied; one returns any error messages, the other does not.

The downloaded code may then be executed by issuing the [Execute](#) command.

**Return Value**

returns 0 - if successful

### Parameters

*Name*

Filename of C Program to compile and download

*Thread*

Thread number where the program is to be compiled for and downloaded into. Valid range 1...7.

*Err*

Caller's supplied buffer for any error messages

*MaxErrLen*

Length of caller's supplied buffer for any error messages

### Example

```
#include "KMotionDLL.h"
CKMotionDLL KMotion;
if (KM.CompileAndLoadCoff(0, "C:\\MyProgram.c", 1)
    MyError();
if (KM.WriteLine(0, "Execute1") MyError();
```

---

```
int ListLocations(int *nlocations, int *list);
```

Returns the number of currently connected KMotion boards and a list of their USB location identifiers

### Return Value

returns 0 - if successful

### Parameters

*nlocations*

pointer to integer where the number of locations should be returned

*List*

pointer to array to be filled in with the list of USB location identifiers

### Example

```
#include "KMotionDLL.h"
CKMotionDLL KM;
int n_boards;
int BoardList[256];
if (KM.ListLocations(&n_boards, BoardList) MyError());
```

# Script Commands

**Commands ( by category):**

## 3PH<N>=<M> <A>

### Description

Sets the assigned PWMs of an axis to the specified magnitude and phase angle for a brushless 3 phase motor.

This command is useful for energizing a coil (or effective coil position). This is often required while initial homing or determining the commutation offset for a 3 phase brushless motor. If an effective coil position is energized, the motor rotor will normally align itself to the coil position. This is similar to the manner in which a stepping motor operates. Since the rotor location is then known, the commutation offset may then be determined. Alternately if an index mark is available, the effective coil position may be rotated by changing the phase angle until the index mark is detected.

### Parameters

#### <N>

Selected Axis for command. Valid range 0...7.

#### <M>

Magnitude of output to apply.

Valid Range is -230 ... +230 PWM units

#### <A>

Commutation angle to be used.  
 Units are in Commutation cycles  
 Only fractional value will be used

***Example***

**3PH0=230 0.5**

**4PH<N>=<M> <A>**

Sets the assigned PWMs of an axis to the specified magnitude and phase angle for a brushless 4 phase motor.

This command is useful for energizing a coil (or effective coil position). This is often required while initial homing or determining the commutation offset for a 4 phase brushless motor. If an effective coil position is energized, the motor rotor will normally align itself to the coil position. This is similar to the manner in which a stepping motor operates. Since the rotor location is then known, the commutation offset may then be determined. Alternately if an index mark is available, the effective coil position may be rotated by changing the phase angle until the index mark is detected.

**Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Magnitude of output to apply.

Valid Range is -250 ... +250 PWM units

**<A>**

Commutation angle to be used.

Units are in Commutation cycles

Only fractional value will be used

**Example****4PH0=250 0.5**

---

**Accel <N>=<A>****or****Accel <N>****Description**

Get or Set the max acceleration (for independent moves and jogs)

**Parameters****<N>**

Selected Axis for command. Valid range 0...7.

**<A>**

The max acceleration. Units are in *Position units* per sec<sup>2</sup>

**Example****Accel0=1000.0**

---

**ADC<N>****Description**

Display current ADC (Analog to Digital Converter). Display range -2048 to 2047

Channels 0-3 are ±10V general purpose inputs

Channels 4-7 are Motor Currents

**Parameters****<N>**

ADC channel

Valid range 0 ... 7

**Example:** ADC 0

---

```
Arc <XC> <YC> <RX> <RY> <θ0> <dθ> <Z0> <A0> <B0> <C0> <Z1> <A1> <B1> <C1> <a>
<b> <c> <d> <tF>
```

**Description**

Place circular (also elliptical or helical) interpolated move into the coordinated motion buffer. See also [KMotion Coordinated Motion](#). A path through space is defined where x and y are changing in an elliptical manner and z, a, b, c are changing in a linear manner forming a portion of a helix. A parametric equation is defined which describes which portion of the path as well as how as a function of time the path is to be traversed. This command can consist of up to 6 axis of coordinated motion. X and Y perform an arc while Z, A, B, and C move linearly.

Although the Arc command may be sent directly, the Arc command is normally generated automatically to perform a planned trajectory by the coordinated motion library or GCode.

(**X<sub>C</sub>,Y<sub>C</sub>**) - center of circle

(**R<sub>X</sub>,R<sub>Y</sub>**) - x radius and y radius

**θ<sub>0</sub>** - initial angle for the beginning of the path

**dθ** - amount of angular change for the path

**Z<sub>0</sub>** - initial Z position of path

**A<sub>0</sub>** - initial A position of path

**B<sub>0</sub>** - initial B position of path

**C<sub>0</sub>** - initial C position of path

**Z<sub>1</sub>** - final Z position of path

**A<sub>1</sub>** - final A position of path

**B<sub>1</sub>** - final B position of path

**C<sub>1</sub>** - final C position of path

3rd order parametric equation where

$$p = \mathbf{a} t^3 + \mathbf{b} t^2 + \mathbf{c} t + \mathbf{d}$$

$p$  is the position along the path as a function of time. When  $p=0$  the  $(x,y,z)$  position will be at the beginning of the path ( $\theta = \theta_0$  and  $z=z_0$ ). When  $p=1$  the  $(x,y,z)$  position will be at the end of the path ( $\theta = \theta_0+d\theta$ , and  $z=z_1$ ).

This motion segment will be performed over a time period of  $t_F$ , where  $t$  varies from  $0 \dots t_F$ . Note that it is not necessary that  $p$  vary over the entire range of  $0 \dots 1$ . This is often the case when there may be an acceleration, constant velocity, and deceleration phase over the path. ie:  $t$  might vary from  $0.0 \rightarrow 0.1$  where  $p$  might vary from  $0.3 \rightarrow 0.7$ .

### Parameters

**<X<sub>C</sub>>** - X center of ellipse, units are position units of x axis

**<Y<sub>C</sub>>** - Y center of ellipse, units are position units of y axis

**<R<sub>X</sub>>** - X radius of ellipse, units are position units of x axis

**<R<sub>Y</sub>>** - Y radius of ellipse, units are position units of y axis

**<θ<sub>0</sub>>** - initial theta position on ellipse, radians (0 radians points in the +x direction)

**<dθ>** - change in theta position on ellipse, radians (+ theta causes CCW motion)

**<Z<sub>0</sub>>** - initial Z position on path, units are position units of z axis

**<A<sub>0</sub>>** - initial A position on path, units are position units of a axis

**<B<sub>0</sub>>** - initial B position on path, units are position units of b axis

**<C<sub>0</sub>>** - initial C position on path, units are position units of c axis

**<Z<sub>1</sub>>** - final Z position on path, units are position units of z axis

**<A<sub>1</sub>>** - final A position on path, units are position units of a axis

**<B<sub>1</sub>>** - final B position on path, units are position units of b axis

**<C<sub>1</sub>>** - final C position on path, units are position units of c axis

**<a>** - parametric equation  $t^3$  coefficient

**<b>** - parametric equation  $t^2$  coefficient

**<c>** - parametric equation *t* coefficient

**<d>** - parametric equation constant coefficient

**<t<sub>F</sub>>** - time for segment

**Example (complete unit circle, centered at 0.5,0.5, no Z, A, B, or C motion, performed in 10 seconds)**

---

```
Arc 0.5 0.5 1.0 1.0 0.0 6.28 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.1 0.0 10.0
```

---

---

```
ArcXZ <XC> <ZC> <RX> <RZ> <θ0> <dθ> <Y0> <A0> <B0> <C0> <Y1> <A1> <B1> <C1>
<a> <b> <c> <d> <tF>
```

---

### Description

Place circular (also elliptical or helical) interpolated move into the coordinated motion buffer. Same as [Arc](#) Command except circular motion is performed in the XZ plane rather than the XY plane.

---

```
ArcYZ <YC> <ZC> <RY> <RZ> <θ0> <dθ> <X0> <A0> <B0> <C0> <X1> <A1> <B1> <C1>
<a> <b> <c> <d> <tF>
```

---

### Description

Place circular (also elliptical or helical) interpolated move into the coordinated motion buffer. Same as [Arc](#) Command except circular motion is performed in the YZ plane rather than the XY plane.

---

```
ArcHex <XC> <YC> <RX> <RY> <θ0> <dθ> <Z0> <A0> <B0> <C0> <Z1> <A1> <B1> <C1>
<a> <b> <c> <d> <tF>
```

---

### Description

Place circular (also elliptical or helical) interpolated move into the coordinated motion buffer. This command is exactly the same as the [Arc](#) command above, except all 13 parameters are specified as 32-bit hexadecimal values which are the binary images of 32-bit floating point values. When generated by a program this is often faster, simpler, and more precise than decimal values. See also [KMotion Coordinated Motion](#).

### Parameters

See above.

**Example (complete unit circle, centered at 0.5,0.5, no Z motion, performed in 10 seconds)**

**Arc 3f000000 3f000000 3f800000 3f800000 0 40c8f5c3 0 0 0 0 40c8f5c3 0 41800000**

---

**ArcHexXZ <X<sub>C</sub>> <Z<sub>C</sub>> <R<sub>X</sub>> <R<sub>Z</sub>> <θ<sub>0</sub>> <dθ> <Y<sub>0</sub>> <A<sub>0</sub>> <B<sub>0</sub>> <C<sub>0</sub>> <Y<sub>1</sub>> <A<sub>1</sub>> <B<sub>1</sub>> <C<sub>1</sub>> <a> <b> <c> <d> <t<sub>F</sub>>**

#### **Description**

Place circular (also elliptical or helical) interpolated move into the coordinated motion buffer. Same as [ArcHex](#) Command except circular motion is performed in the XZ plane rather than the XY plane.

---

**ArcHexYZ <Y<sub>C</sub>> <Z<sub>C</sub>> <R<sub>Y</sub>> <R<sub>Z</sub>> <θ<sub>0</sub>> <dθ> <X<sub>0</sub>> <A<sub>0</sub>> <B<sub>0</sub>> <C<sub>0</sub>> <X<sub>1</sub>> <A<sub>1</sub>> <B<sub>1</sub>> <C<sub>1</sub>> <a> <b> <c> <d> <t<sub>F</sub>>**

#### **Description**

Place circular (also elliptical or helical) interpolated move into the coordinated motion buffer. Same as [ArcHex](#) Command except circular motion is performed in the YZ plane rather than the XY plane.

---

**BacklashAmount<N>=<A>**

or

**BacklashAmount<N>**

#### **Description**

Sets or gets the amount of Backlash Compensation Offset to be applied.

See also [BacklashMode](#) and [BacklashRate](#).

#### **Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<A>**

Floating point Backlash Compensation Amount in units of Steps or Counts.

#### **Example**

**BacklashAmount=15.5****BacklashMode<N>=<M>**

or

**BacklashMode<N>*****Description***

Sets or gets the Backlash Compensation mode from either BACKLASH\_OFF (0) to BACKLASH\_LINEAR (1). When the backlash mode is set to Linear mode, whenever the commanded destination begins moving in the positive direction, a positive offset of the amount, [BacklashAmount](#), will be applied. The offset will be ramped upward as a linear function of time at the rate specified as the [BacklashRate](#). Whenever the commanded destination begins moving in the negative direction the offset will be removed by ramping downward toward zero at the same rate.

If the the Backlash Compensation mode is set to BACKLASH\_OFF (0), no backlash compensation will be applied.

***Parameters*****<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Backlash Compensation Mode setting. Currently 0 or 1.

***Example*****BacklashMode0=1****BacklashRate<N>=<R>**

or

**BacklashRate<N>*****Description***

Sets or gets the rate at which the amount of Backlash Compensation Offset will be applied.

See also [BacklashMode](#) and [BacklashAmount](#).

### **Parameters**

#### **<N>**

Selected Axis for command. Valid range 0...7.

#### **<A>**

Floating point Backlash Compensation Rate in units of Steps or Counts per second.

### **Example**

**BacklashRate=1000.0**

---

## **BegRapidBuf**

### **Description**

Inserts into coordinated move buffer a command to indicate Rapid is in progress and to use Rapid FRO.

### **Parameters**

None

### **Example**

**BegRapidBuf**

---

## **CheckDone<N>**

### **Description**

Displays:

1 if axis N has completed its motion

0 if axis N has not completed its motion

-1 if the axis is disabled

## Parameters

<N>

Selected Axis for command. Valid range 0...7.

### Example

CheckDone0

---

## CheckDoneBuf

### Description

Displays the status of the Coordinated Motion Buffer. **KMotion** contains a Coordinated Motion Buffer where move segments (linear and arcs) and I/O commands may be downloaded and executed in real time.

Displays:

- 1 if all coordinated move segments have completed
- 0 if all coordinated move segments have not completed
- 1 if any axis in the [defined coordinate system](#) is disabled

## Parameters

None

### Example

CheckDoneBuf

---

## CheckDoneGather

### Description

Displays the status of a data gather operation. **KMotion** contains a mechanism for capturing data from a variety of sources in real time. This mechanism is utilized when capturing data for [Bode plots](#) and [Step response](#) plots. It is also available for general purpose use. See the [data gathering example](#).

Displays:

- 1 if data gather is completed

0 if data gather has not completed

### **Parameters**

None

### **Example**

**CheckDoneGather**

---

## **CheckDoneXYZABC**

### **Description**

Displays status of a commanded [MoveXYZABC](#) command. See also [DefineCS6](#).

Displays:

1 if all axes in the defined coordinate system have completed their motion

0 if any axis in the defined coordinate system has not completed its motion

-1 if any axis in the defined coordinate system is disabled

### **Parameters**

None

### **Example**

**CheckDoneXYZABC**

---

## **CheckThread<N>**

### **Description**

Checks whether a User Program Thread is currently executing. Returns 1 if executing, 0 if not executing.

### **Parameters**

<N>

Thread number specified as a decimal number. Valid range 1...7

***Example*****CheckThread0**

---

**ClearBit<N>*****Description***

Clears an actual I/O bit or virtual I/O bit. Note that actual I/O bits must be previously defined as an output, see [SetBitDirection](#)

***Parameters*****<N>**

Bit number specified as a decimal number. Accepted range 0...2047

***Example*****ClearBit0**

---

**ClearBitBuf<N>*****Description***

Inserts into the coordinated move buffer a command to clear an I/O bit (actual IO bits must be defined as an output, see [SetBitDirection](#))

***Parameters*****<N>**

Bit Number to clear. Accepted range 0...2047

***Example*****ClearBitBuf0**

---

**ClearFlashImage*****Description***

Prepare to download FLASH firmware image. Sets entire RAM flash image to zero

### **Parameters**

None.

### **Example**

**ClearFlashImage**

---

**CommutationOffset<N>=<X>**

**or**

**CommutationOffset<N>**

### **Description**

Get or Set 3 or 4 phase commutation offset. When brushless commutation is performed, the desired Output Magnitude is distributed and applied to the various motor coils as a function of position. The commutation offset shifts the manner in which the Output Magnitude is applied.

For a 3 phase brushless output mode, commutation offset is used in the following manner.

$$\text{PhaseA} = \text{OutputMagnitude} * \sin((\text{Position} + \text{CommutationOffset}) * \text{invDistPerCycle} * 2\pi)$$

$$\text{PhaseB} = \text{OutputMagnitude} * \sin((\text{Position} + \text{CommutationOffset}) * \text{invDistPerCycle} * 2\pi + 2\pi/3)$$

$$\text{PhaseC} = \text{OutputMagnitude} * \sin((\text{Position} + \text{CommutationOffset}) * \text{invDistPerCycle} * 2\pi + 4\pi/3)$$

For a 4 phase brushless output mode, commutation offset is used in the following manner.

$$\text{PhaseA} = \text{OutputMagnitude} * \sin((\text{Position} + \text{CommutationOffset}) * \text{invDistPerCycle} * 2\pi)$$

$$\text{PhaseB} = \text{OutputMagnitude} * \cos((\text{Position} + \text{CommutationOffset}) * \text{invDistPerCycle} * 2\pi)$$

See also [invDistPerCycle](#) and [Configuration Parameters](#).

### **Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<X>**

Offset in units of Position.

### ***Example***

**CommutationOffset0=100.0**

---

## **ConfigSpindle <T> <A> <U> <W> <C>**

### ***Description***

Enables/Disables and configures the firmware to monitor Spindle Speed and Position to allow reporting of Spindle Speed and to perform Threading operations.

See also: [TrigThread](#) and [GetSpindleRPS](#)

### ***Parameters***

#### **<T>**

Spindle Sensor Type. 0 - disables spindle measurement, 1 - defines the sensor type as a quadrature encoder .

#### **<A>**

Axis - Defines the Axis Channel that will maintain the Spindle Position. Note this is not a Encoder input channel. Rather it is the Axis Channel that has a Encoder input Channel defined. Valid range 0 ...7.

#### **<U>**

Update Time - delta time for measurement. This is the amount of time between Spindle Position samples used to calculate the current speed. Speed = Delta Position/Delta Time. A longer time period will allow for a more accurate speed measurement, especially at low speeds and if a low resolution encoder is used. A shorter Update Time will make the speed measurement to be more responsive as it changes. Units of seconds. Typical value 0.2 seconds

#### **<W>**

Tau - low pass filter time constant for threading. Pseudo Time along a time dependent trajectory path is adjusted based on spindle position. The Pseudo Time is smoothed using a low pass filter

with a time constant of Tau to avoid making too abrupt changes of position, velocity or acceleration.  
Units of seconds. Typical value 0.1 seconds

**<C>**

Counts per Revolution. Number of encoder counts per full revolution of the Spindle.

***Example***

**ConfigureSpindle 1 0 0.2 0.1 4096.0**

---

**D<N>=<M>**

**or**

**D<N>**

***Description***

Get or Set [PID](#) derivative Gain.

***Parameters***

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Derivative Gain value. The units of the derivative gain are in Output Units/Position Units x [Servo Sample Time](#).

***Example***

**D0=10.0**

---

**DAC<N> <M>**

***Description***

DAC to value. DACs 0...3 have  $\pm 10$  Volt ranges, DACs 4...7 have 0...4 Volt ranges. See also [Analog Status Screen](#).

### Parameters

**<N>**

DAC channel to set. Valid Range 0...7.

**<M>**

DAC value to set in counts. Valid Range -2048...2047.

### Example

**DAC0=2000**

---

**DeadBandGain<N>=<M>**

**or**

**DeadBandGain<N>**

### Description

Get or Set gain while error is within the [deadband range](#). See [DeadBand Description](#). See [Servo Flow Diagram](#).

### Parameters

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Gain to be applied. A value of 1.0 will have normal gain while within the deadband. A value less than 1.0 will have reduced gain within the deadband.

### Example

**DeadBandGain0=0.5**

**DeadBandRange<N>=<M>**

or

**DeadBandRange<N>*****Description***

Get or Set range where [deadband\\_gain](#) is to be applied. See [DeadBand Description](#). See [Servo Flow Diagram](#).

**Parameters****<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

±Range in Position units,

***Example***

**DeadBandRange0=1.0**

**DefineCS<X> <Y> <Z> <A> <B> <C>**

or

**DefineCS*****Description***

Set or get the defined X Y Z A B C coordinate system axis assignments for up to 6 axes of coordinated motion. Unused axis are assigned an axis channel of -1.

See also [Coordinated Motion](#).

**Parameters****<X>**

Assigned Axis channel number for X. Valid range -1 ... 7.

Use -1 if axis is not defined.

#### <Y>

Assigned Axis channel number for Y. Valid range -1 ... 7.

Use -1 if axis is not defined.

#### <Z>

Assigned Axis channel number for Z. Valid range -1 ... 7.

Use -1 if axis is not defined.

#### <A>

Assigned Axis channel number for A. Valid range -1 ... 7.

Use -1 if axis is not defined.

#### <B>

Assigned Axis channel number for B. Valid range -1 ... 7.

Use -1 if axis is not defined.

#### <C>

Assigned Axis channel number for C. Valid range -1 ... 7.

Use -1 if axis is not defined.

### ***Example***

#### **DefineCS**

**DefineCS = 0 1 2 3 4 -1**

---

**DefineCSEX<X> <Y> <Z> <A> <B> <C> <U> <V>**

**or**

**DefineCSEX**

## Description

Set or get the defined X Y Z A B C coordinate system axis assignments for up to 8 axes of coordinated motion. Unused axis are assigned an axis channel of -1.

See also [Coordinated Motion](#).

## Parameters

### <X>

Assigned Axis channel number for X. Valid range -1 ... 7.  
Use -1 if axis is not defined.

### <Y>

Assigned Axis channel number for Y. Valid range -1 ... 7.  
Use -1 if axis is not defined.

### <Z>

Assigned Axis channel number for Z. Valid range -1 ... 7.  
Use -1 if axis is not defined.

### <A>

Assigned Axis channel number for A. Valid range -1 ... 7.  
Use -1 if axis is not defined.

### <B>

Assigned Axis channel number for B. Valid range -1 ... 7.  
Use -1 if axis is not defined.

### <C>

Assigned Axis channel number for C. Valid range -1 ... 7.  
Use -1 if axis is not defined.

### <U>

Assigned Axis channel number for U. Valid range -1 ... 7.  
Use -1 if axis is not defined.

**<V>**

Assigned Axis channel number for V. Valid range -1 ... 7.  
Use -1 if axis is not defined.

***Example***

**DefineCSEX**

**DefineCSEX = 0 1 2 3 4 5 6 7**

---

**Dest<N>=<M>**

**or**

**Dest<N>**

***Description***

Set or get the last commanded destination for an axis. The Dest (destination) is normally set (or continuously updated) as the result of a motion command (Move, Jog, or Coordinated motion), but may also be set with this command if no motion is in progress.

***Parameters***

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Value to set in Position units. Valid range - any.

***Example***

**Dest0=100**

**or**

**Dest0****DisableAxis<N>****Description**

Kill any motion and disable motor. Any associated output PWM channels for the axis will be set to 0R mode.

**Parameters****<N>**

Selected Axis for command. Valid range 0...7.

**Example****DisableAxis0****Echo <S>****Description**

Echo character string back to the [Console Screen](#).

**Parameters****<S>**

Any character string < 80 characters

**Example****Echo Hello****EnableAxis<N>****Description**

Set an Axis' *destination* to the Current Measured Position and enable the axis. See also [EnableAxisDest](#) to explicitly set the desired destination for the axis. Note for a MicroStepper Axis (which normally has no measured position) this command will leave the Axis' destination unchanged..

**Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**Example**

**Enable0**

---

**EnableAxisDest<N> <M>**

**Description**

Set an Axis' *destination* to the specified position and enable the axis. See also [EnableAxis](#) to set the desired destination to the current measured position.

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Destination for the axis. Position units. Valid range - any.

**Example**

**EnableAxisDest0 1000.0**

---

**Enabled<N>**

**Description**

Display whether the specified axis is enabled, 1 - if currently enabled, 0 - if not enabled.

Note: to enable an axis use [EnableAxis](#) or [EnableAxisDest](#).

**Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**Example**

**Enabled0**

---

## EndRapidBuf

### **Description**

Inserts into coordinated move buffer a command to indicate Rapid has been completed and to no longer use Rapid FRO.

### **Parameters**

None

### **Example**

**EndRapidBuf**

---

## EntryPoint<N> <H>

### **Description**

Set execution start address of user thread to specified address. This operation is normally performed automatically when downloading a user program.

### **Parameters**

**<N>**

User Thread number to set. Decimal number. Valid range 1...7.

**<H>**

Start address. 32 bit Hex number.

### **Example**

**Entrypoint1 80030000**

---

## ExecBuf

### **Description**

Execute the contents of the coordinated motion buffer. Use [CheckDoneBuf](#) to determine when the buffer has been fully executed. See also [Coordinated Motion](#).

**Parameters**

None

**Example**

**ExecBuf**

---

**ExecTime****Description**

Displays the amount of the Coordinated Motion Buffer that has been already executed in terms of Time. **KMotion** contains a Coordinated Motion Buffer where move segments (linear and arcs) and I/O commands may be downloaded and executed in real time. This command is useful for determining how long before the Coordinated Motion Buffer will complete. For example, if a number of segments have been downloaded where their total execution time is 10 seconds, and they are currently in progress of being executed, and the ExecTime command reports that 8 seconds worth of segments have been executed, then the remaining time before the queue completes (or starves for data) would be 2 seconds. This command is useful for applications where it is important not to download data too far ahead so changes to the Trajectory may be made. The value returned is a floating point decimal value in Seconds with 3 decimal places. If the Coordinated Motion has already completed the amount of time will be a negative value whose magnitude is the total time that was executed. See also [Coordinated Motion](#).

Displays:

Executed time in seconds as a floating point decimal number with 3 decimal places

ie. 10.123

If the buffer has already completed the value will be negative

ie. -10.123

**Parameters**

None

**Example**

**ExecTime**

---

**Execute<N>****Description**

Begin execution of thread. Execution begins at the previously specified thread entry point.

See also [C Program Screen](#).

#### **Parameters**

**<N>**

Thread number to begin execution. Decimal number. Valid range 1...7.

#### **Example**

**Execute1**

---

**FFAccel<N>=<M>**

**or**

**FFAccel<N>**

#### **Description**

Set or get Acceleration *feed forward* for axis.

See also [feed forward tuning](#).

#### **Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Feed forward value. units are in Output units per Input Units per sec<sup>2</sup>.

#### **Example**

**FFAccel0=100.0**

**or**

**FFAccel0**

---

**FFVel<N>=<M>**

or

**FFVel<N>****Description**

Set or get Velocity *feed forward* for axis.

See also [feed forward tuning](#).

**Parameters****<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Feed forward value. units are in Output units per Input Units per sec.

**Example**

**FFVel0=100.0**

or

**FFVel0**

---

**Flash****Description**

Flash current *user programs*, persistent memory area, all axes configurations, tuning, and filter parameters to non-volatile memory. The entire state of the **KMotion** is saved to FLASH memory. Any active user programs will be paused during the flash operation

**Parameters**

None

**Example**

## Flash

---

### FlushBuf

#### ***Description***

Informs KFLOP that the Coordinated Motion Buffer has been Flushed. This permits KFLOP to execute to the end of the buffer without performing protection against buffer starvation which would normally perform Feed Rate reduction in an attempt to avoid buffer underflow.

#### ***Parameters***

None

#### ***Example***

### FlushBuf

---

### FPGA<N> <M>

---

#### ***Description***

Directly write an 8-bit value to an FPGA register. Should be only used with caution.

#### ***Parameters***

##### **<N>**

FPGA Register address to write as a decimal number. Valid range 0...1023.

##### **<M>**

8-bit value as a decimal number. Valid range 0...255.

#### ***Example***

### FPGA 261 192

---

### FPGAW<N> <M>

---

#### ***Description***

Directly write a 16-bit value to an FPGA register. Should be only used with caution.

### **Parameters**

#### **<N>**

FPGA Register address to write as a decimal number. Valid range 0...1023.

#### **<M>**

16-bit value as a decimal number. Valid range 0...65536.

### **Example**

**FPGAW 5 263**

---

## **GatherMove<N> <M> <L>**

### **Description**

Performs a profiled move on an axis of the specified distance while [gathering](#) the specified number of points of data. This command is used while gathering data for the [Step Response Screen](#) plots.

### **Parameters**

#### **<N>**

Selected Axis for command. Valid range 0...7.

#### **<M>**

Distance to move. Units are Position Units. Valid Range - any.

#### **<L>**

Number of servo samples to gather. Valid Range - 1...40000

### **Example**

**GatherMove0 1000.0 2000**

**GatherStep<N> <M> <L>*****Description***

Performs a step on an axis of the specified distance while [gathering](#) the specified number of points of data. This command is used while gathering data for the [Step Response Screen](#) plots.

***Parameters*****<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Distance to step. Units are Position Units. Valid Range - any.

**<L>**

Number of servo samples to gather. Valid Range - 1...40000

***Example***

**GatherStep0 1000.0 2000**

**GetAllDestHex*****Description***

Get all 8 Axis Destinations as 64 bit doubles, each as 2 32-bit Hexadecimal Values (low|high)

***Parameters***

None

***Example***

Axis 0 Destination of 1000.0

GetAllDestHex

```
00000000 408F4000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000  
00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000
```

**GetBitDirection<N>**

**Description**

Displays whether an IO bit N (0...2047) is defined as input (0) or output (1)

**Parameters**

**<N>**

I/O bit number. Accepted range 0...2047

**Example**

**GetBitDirection0**

---

**GetGather <N>****Description**

Upload N data points from previous [GatherMove](#) or [GatherStep](#) command. Captured commanded destination, measured position, and output are uploaded as hex values (that represent binary images of 32-bit floating point values). Eight samples (24 values) per line.

**Parameters**

**<N>**

Number of points to upload. Valid range 1...40000.

**Example**

**GetGather 1000**

---

**GetGatherDec<N>****Description**

Reads a single word from the [Gather Buffer](#) at the specified offset. A single 32-bit value displayed as a signed decimal integer number will be displayed.

**Parameters**

**<N>**

Offset into gather buffer, specified as a decimal offset of 32 bit words. Valid range 0...1999999

**Example**

**GetGatherDec 1000**

---

**GetGatherHex<N> <M>****Description**

Reads multiple words from the [Gather Buffer](#) beginning at the specified offset. Hexadecimal values will be displayed that will represent binary images of the contents of the gather buffer as 32 bit words.

**Parameters****<N>**

Offset into gather buffer, specified as a decimal offset of 32 bit words. Valid range 0...1999999

**<M>**

Number of 32 bit words to display. Decimal integer. Valid range 1...2000000

**Example**

**GetGatherHex 0 100**

---

**GetInject<N> <M>****Description**

Display results of signal injection and gathering. Bode Plot measurement involves injecting a signal and measuring the response for each of N\_CPLX (2048) samples. This command gets the result from the injection. 3 values per sample are uploaded. Injection value, position response (relative to destination), and servo output. All 3 values are printed as hexadecimal values which represent the image of a 32-bit floating point value. 8 samples (24 hex values) are printed per line.

**Parameters**

None

**Example**

**GetInject**

---

**GetPersistDec<N>**

## Description

Read a single word from the *Persist Array* at the specified offset a single 32-bit value displayed as a **signed decimal number**. The persist array is a general purpose array of N\_USER\_DATA\_VARS (100) 32-bit values that is accessible to the host as well as **KMotion C Programs**. It may be used to share parameters, commands, or information between programs.

C Programs may access this array as the integer array:

```
persist(userData[n];
```

It also resides in the **KMotion** Persist memory structure so that if memory is flashed, the value will be present at power up.

See also [GetPersistHex](#), [SetPersistDec](#), [SetPersistHex](#)

## Parameters

**<N>**

Offset into the integer array. Valid range 0...99.

## Example

**GetPersistDec 10**

## **GetPersistHex<N>**

### Description

Read a single word from the *Persist Array* at the specified offset a single 32-bit value displayed as an **unsigned hexadecimal number**. The persist array is a general purpose array of N\_USER\_DATA\_VARS (100) 32-bit values that is accessible to the host as well as **KMotion C Programs**. It may be used to share parameters, commands, or information between programs.

C Programs may access this array as the integer array:

```
persist(userData[n];
```

It also resides in the **KMotion** Persist memory structure so that if memory is flashed, the value will be present at power up.

See also [GetPersistDec](#), [SetPersistDec](#), [SetPersistHex](#)

## Parameters

**<N>**

Offset into the integer array. Valid range 0...99.

### ***Example***

#### **GetPersistHex 10**

---

#### **GetSpindleRPS**

##### ***Description***

Reports the current Spindle Speed in revolutions per second.

See also [ConfigSpindle](#) and [TrigThread](#)

##### ***Parameters***

### ***Example***

#### **GetSpindleRPS**

---

#### **GetStatus**

##### ***Description***

Upload Main Status record in hex format. **KMotion** provides a means of quickly uploading the most commonly used status. This information is defined in the PC-DSP.h header file as the MAIN\_STATUS structure. The entire structure is uploaded as a binary image represented as 32-bit hexadecimal values.

##### ***Parameters***

None

### ***Example***

#### **GetStatus**

---

#### **GetStopState**

##### ***Description***

Reports the state of any feedhold stop in progress. 0 = not stopping, 1=stopping a coord motion, 2=stopping an independent motion of one or more axes, 3=fully stopped, 4=independent motion of all related axes fully stopped. This returns the KFLOP C program variable - CS0\_StoppingState. A feedhold stop can be initiated from C code or from the Console Command [StopImmediate](#).

**Parameters**

None

***Example*****GetStopState****GetVirtualBits*****Description***

KFLOP supports an extended range of 1024 virtual I/O bits. These bits reside in KFLOP's memory as a table of 32 32-bit words. The command GetVirtualBits is used to upload KFLOP virtual bit words to the PC in bulk. Any consecutive group of words can be uploaded with a single command. The words are uploaded as hexadecimal values.

**Parameters**

Starting word in decimal

Number of words in decimal

***Example***

If the top 4 bits of virtual bit word #1 (the second word, bits 1084, 1085, 1086, 1087) are set with all other bits zero, then the command shown below to display 3 words starting at word #1 would display:

```
GetVirtualBits 1 3
F0000000 0 0
```

|<N>=<M>

or

|<N>

***Description***

Get or Set [PID](#) Integral Gain.

**Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Integral Gain value. The units of the derivative gain are in Output Units x Position Units x [Servo Sample Time](#).

### **Example**

**I0=10.0**

or

**I0****IIR<N> <M>=<A1> <A2> <B0> <B1> <B2>**

or

**IIR<N> <M>**

### **Description**

Set or get IIR Z domain servo filter.

See also [IIR Filter Screen](#)

### **Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Filter number for axis. Valid range 0...2.

**<A1> <A2> <B0> <B1> <B2>**

Filter coefficients represented as floating point decimal values.

### ***Example***

**IIR0 0=1.5 2.5 -3.5 4.5 5.5**

or

**IIR0 0**

---

**Inject<N> <F> <A>**

### ***Description***

A Inject random stimulus into an axis with the specified cutoff frequency and amplitude. Useful for generating [Bode plots](#).

### ***Parameters***

**<N>**

Selected Axis for command. Valid range 0...7.

**<F>**

Cutoff Frequency in Hz. Valid range - any.

**<A>**

Amplitude in position units. Valid range - any.

### ***Example***

**Inject0 100.0 20.0**

---

**InputChan<M> <N>=<C>**

or

**InputChan<M> <N>**

### ***Description***

Get or Set the first or second *Input Channel* of an axis. See description of this parameter on the [Configuration Screen](#).

## Parameters

**<M>**

Selected input channel. Valid range 0...1.

**<N>**

Selected Axis for command. Valid range 0...7.

**<C>**

Channel number to assign. Valid range 0...7.

**Example (set first input channel of axis 3 to 3)**

**InputChan0 3=3**

or

**InputChan0 3**

---

**InputGain<M> <N>=<G>**

or

**InputGain<M> <N>**

## Description

Set or get first or second Input Gain of an axis. See description of this parameter on the [Configuration Screen](#).

## Parameters

**<M>**

Selected input channel. Valid range 0...1.

**<N>**

Selected Axis for command. Valid range 0...7.

**<C>**

Input Gain. Valid range - any.

**Example**

**InputGain0 3=1.0****InputMode<N>=<M>****or****InputMode<N>*****Description***

Set or get the position input mode for an axis. See description of this parameter on the [Configuration Screen](#).

Valid modes are (from PC-DSP.h):

```
#define NO_INPUT_MODE 0
#define ENCODER_MODE 1
#define ADC_MODE 2
#define RESOLVER_MODE 3
#define USER_INPUT_MODE 4
```

***Parameters*****<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Mode. Valid range 1...4

***Example*****SetInputModule0=1****InputOffset<M> <N>=<O>****or****InputOffset<M> <N>*****Description***

Set or get first or second Input Offset of an axis. See description of this parameter on the [Configuration Screen](#).

### Parameters

**<M>**

Selected input channel. Valid range 0...1.

**<N>**

Selected Axis for command. Valid range 0...7.

**<O>**

Input Offset. Valid range - any.

### Example

**InputOffset0 3=0.0**

---

**InvDistPerCycle<N>=<X>**

### Description

Get or Set distance per cycle (specified as an inverse) of an axis. May specify the cycle of either a Stepper or Brushless Motor.

See description of this parameter on the [Configuration Screen](#).

### Parameters

**<N>**

Selected Axis for command. Valid range 0...7.

**<X>**

Inverse (reciprocal) of distance for a complete cycle. Inverse position units. Should be specified exactly or with very high precision (double precision accuracy ~ 15 digits). Valid range - any.

### Example

**InvDistPerCycle0=0.05**

---

**Jerk<N>=<J>**

or

**Jerk<N>****Description**

Get or Set the max [jerk](#) (for independent moves and jogs)

**Parameters****<N>**

Selected Axis for command. Valid range 0...7.

**<J>**

The max Jerk. Units are in *Position units* per sec<sup>3</sup>

**Example**

**Jerk0=10000.0**

---

**Jog<N>=<V>****Description**

Move at constant velocity. Uses [Accel](#) and [Jerk](#) parameters for the axis to accelerate from the current velocity to the specified velocity. Axis should be already enabled. Specify zero velocity to decelerate to a stop.

**Parameters****<N>**

Selected Axis for command. Valid range 0...7.

**<V>**

new Velocity in position units/second. Valid range - any.

**Example**

**Jog0=-200.5**

---

## **JogAtAccel<N>=<V> <A>**

### ***Description***

Move Axis N at Velocity V using specified Acceleration. Uses Jerk parameter for the axis. Specify zero Velocity to decelerate to stop.

### ***Parameters***

**<N>**

Selected Axis for command. Valid range 0...7.

**<V>**

New Velocity in position units/second. Valid range - any.

**<A>**

Specified Acceleration.

### ***Example***

**JogAtAccel0=-200.5 5000.0**

---

## **Kill<N>**

### ***Description***

Stop execution of a user thread.

### ***Parameters***

**<N>**

Thread to halt. Valid range 1..7

### ***Example***

**Kill0**

---

**Lead<N>=<M>**

or

**Lead<N>*****Description***

Set or get [Lead Compensation](#) for an axis. Lead Compensation is used to compensate for lag caused by motor inductance.

**Parameters****<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Lead Compensation. Valid range - any.

***Example***

**Lead0=10.0**

or

**Lead0**

---

**LimitSwitch<N>=<H>*****Description***

Configures Limit Switch Options. Specify Hex value where:

See also [Configuration Screen](#).

**Parameters****<N>**

Selected Axis for command. Valid range 0...7.

**<H>**

32-bit hexadecimal value:

Bit 0 1=Stop Motor on Neg Limit, 0=Ignore Neg limit

Bit 1 1=Stop Motor on Pos Limit, 0=Ignore Pos limit

Bit 2 Neg Limit Polarity 0=stop on high, 1=stop on low

Bit 3 Pos Limit Polarity 0=stop on high, 1=stop on low

Bits 4-7 Action - 0 Kill Motor Drive

1 Disallow drive in direction of limit

2 Stop movement

Bits 16-23 Neg Limit Bit number

Bits 24-31 Pos Limit Bit number

***Example***

**LimitSwitch2 0C0D0003**

---

**Linear < $X_0$ > < $Y_0$ > < $Z_0$ > < $A_0$ > < $B_0$ > < $C_0$ > < $X_1$ > < $Y_1$ > < $Z_1$ > < $A_1$ > < $B_1$ > < $C_1$ > < $a$ > < $b$ > < $c$ > < $d$ > < $t_f$ >**

***Description***

Place linear (in 6 dimensions) interpolated move into the coordinated motion buffer. See also [KMotion Coordinated Motion](#). A path through space is defined where  $x$ ,  $y$ ,  $z$ ,  $a$ ,  $b$ , and  $c$  are changing in a linear manner. A parametric equation is defined which describes which portion of the path as well as how as a function of time the path is to be traversed.

Although the Linear command may be sent directly, the Linear command is normally generated automatically to perform a planned trajectory by the coordinated motion library or GCode.

( $X_0, Y_0, Z_0, A_0, B_0, C_0$ ) - beginning of path

( $X_1, Y_1, Z_1, A_1, B_1, C_1$ ) - end of path

3rd order parametric equation where

$$p = \mathbf{a} t^3 + \mathbf{b} t^2 + \mathbf{c} t + \mathbf{d}$$

$p$  is the position along the path as a function of time. When  $p=0$  the  $(x,y,z,A)$  position will be at the beginning of the path. When  $p=1$  the  $(x,y,z,A)$  position will be at the end of the path.

This motion segment will be performed over a time period of  $t_F$ , where  $t$  varies from  $0 \dots t_F$ . Note that it is not necessary that  $p$  vary over the entire range of  $0 \dots 1$ . This is often the case when there may be an acceleration, constant velocity, and deceleration phase over the path. ie:  $t$  might vary from  $0.0 \rightarrow 0.1$  where  $p$  might vary from  $0.3 \rightarrow 0.7$ .

### Parameters

**$\langle X_0 \rangle$**  - X begin point

**$\langle Y_0 \rangle$**  - Y begin point

**$\langle Z_0 \rangle$**  - Z begin point

**$\langle A_0 \rangle$**  - A begin point

**$\langle B_0 \rangle$**  - B begin point

**$\langle C_0 \rangle$**  - C begin point

**$\langle X_0 \rangle$**  - X end point

**$\langle Y_1 \rangle$**  - Y end point

**$\langle Z_1 \rangle$**  - Z end point

**$\langle A_1 \rangle$**  - A end point

**$\langle B_1 \rangle$**  - B end point

**$\langle C_1 \rangle$**  - C end point

**$\langle \theta_1 \rangle$**  - initial theta position on ellipse, radians (0 radians points in the  $+x$  direction)

**$\langle a \rangle$**  - parametric equation  $t^3$  coefficient

**$\langle b \rangle$**  - parametric equation  $t^2$  coefficient

**$\langle c \rangle$**  - parametric equation  $t$  coefficient

**$\langle d \rangle$**  - parametric equation constant coefficient

**$\langle t_F \rangle$**  - time for segment

**Example**

```
Linear 0.0 0.0 0.0 0.0 0.0 0.0 1.0 1.0 1.0 1.0 1.0 0.0 0.0 1.0 0.0 1.0
```

---

```
LinearEx <X0> <Y0> <Z0> <A0> <B0> <C0> <U0> <V0> <X1> <Y1> <Z1> <A1> <B1> <C1>
<U1> <V1> <a> <b> <c> <d> <tF>
```

**Description**

Place linear (in 8 dimensions) interpolated move into the coordinated motion buffer. See also [KMotion Coordinated Motion](#). A path through space is defined where  $x, y, z, a, b, c, u$  and  $v$  are changing in a linear manner. A parametric equation is defined which describes which portion of the path as well as how as a function of time the path is to be traversed.

Although the Linear command may be sent directly, the Linear command is normally generated automatically to perform a planned trajectory by the coordinated motion library or GCode, however currently the GCode Interpreters available only support 6 axes of simultaneous motion.

$(X_0, Y_0, Z_0, A_0, B_0, C_0, U_0, V_0)$  - beginning of path

$(X_1, Y_1, Z_1, A_1, B_1, C_1, U_1, V_1)$  - end of path

3rd order parametric equation where

$$p = a t^3 + b t^2 + c t + d$$

$p$  is the position along the path as a function of time. When  $p=0$  the  $(x,y,z,A)$  position will be at the beginning of the path. When  $p=1$  the  $(x,y,z,A)$  position will be at the end of the path.

This motion segment will be performed over a time period of  $t_F$ , where  $t$  varies from  $0 \dots t_F$ . Note that it is not necessary that  $p$  vary over the entire range of  $0 \dots 1$ . This is often the case when there may be an acceleration, constant velocity, and deceleration phase over the path. ie:  $t$  might vary from  $0.0 \rightarrow 0.1$  where  $p$  might vary from  $0.3 \rightarrow 0.7$ .

**Parameters**

**<X<sub>0</sub>>** - X begin point

**<Y<sub>0</sub>>** - Y begin point

**<Z<sub>0</sub>>** - Z begin point

**<A<sub>0</sub>>** - A begin point

**<B<sub>0</sub>>** - B begin point

**<C<sub>0</sub>>** - C begin point

**<U<sub>0</sub>>** - U begin point

**<V<sub>0</sub>>** - V begin point

**<X<sub>0</sub>>** - X end point

**<Y<sub>1</sub>>** - Y end point

**<Z<sub>1</sub>>** - Z end point

**<A<sub>1</sub>>** - A end point

**<B<sub>1</sub>>** - B end point

**<C<sub>1</sub>>** - C end point

**<U<sub>1</sub>>** - U end point

**<V<sub>1</sub>>** - V end point

**<θ<sub>1</sub>>** - initial theta position on ellipse, radians (0 radians points in the +x direction)

**<a>** - parametric equation  $t^3$  coefficient

**<b>** - parametric equation  $t^2$  coefficient

**<c>** - parametric equation  $t$  coefficient

**<d>** - parametric equation constant coefficient

**<t<sub>F</sub>>** - time for segment

### **Example**

**LinearEx 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 1.0 1.0 1.0 1.0 1.0 1.0 1.0 0.0 0.0 1.0 0.0 1.0**

---

**LinearHex <X<sub>0</sub>> <Y<sub>0</sub>> <Z<sub>0</sub>> <A<sub>0</sub>> <B<sub>0</sub>> <C<sub>0</sub>> <X<sub>1</sub>> <Y<sub>1</sub>> <Z<sub>1</sub>> <A<sub>1</sub>> <B<sub>1</sub>> <C<sub>1</sub>> <a> <b> <c> <d> <t<sub>F</sub>>**

### **Description**

Place linear (in 6 dimensions) interpolated move into the coordinated motion buffer. This command is exactly the same as the [Linear](#) command above, except all 17 parameters are specified as 32-bit hexadecimal values which are the binary images of 32-bit floating point values. When generated by

a program this is often faster, simpler, and more precise than decimal values. See also [KMotion Coordinated Motion](#).

### **Parameters**

See above.

### **Example**

```
LinearHex 0 0 0 0 0 0 3F800000 3F800000 3F800000 3F800000 3F800000 3F800000 0 0
3F800000 0 3F800000
```

---

```
LinearHexEx <X0> <Y0> <Z0> <A0> <B0> <C0> <U0> <V0> <X1> <Y1> <Z1> <A1> <B1>
<C1> <U1> <V1> <a> <b> <c> <d> <tF>
```

### **Description**

Place linear (in 8 dimensions) interpolated move into the coordinated motion buffer. This command is exactly the same as the [LinearEx](#) command above, except all 21 parameters are specified as 32-bit hexadecimal values which are the binary images of 32-bit floating point values. When generated by a program this is often faster, simpler, and more precise than decimal values. See also [KMotion Coordinated Motion](#).

### **Parameters**

See above.

### **Example**

```
LinearHex 0 0 0 0 0 0 0 3F800000 3F800000 3F800000 3F800000 3F800000
3F800000 3F800000 0 0 3F800000 0 3F800000
```

---

```
LinHex1 <X1> <Y1> <Z1> <A1> <B1> <C1> <a> <b> <c> <d> <tF>
```

### **Description**

Place linear (in 6 dimensions) interpolated move into the coordinated motion buffer. This command is exactly the same as the [LinearHex](#) command above, except the beginning point is not specified and is assumed to be the endpoint of the previous [LinearHex](#) or [LinHex1](#) command. See also [KMotion Coordinated Motion](#).

### **Parameters**

See above.

***Example***

**LinHex1 3F800000 3F800000 3F800000 3F800000 3F800000 3F800000 0 0 3F800000 0 3F800000**

---

**LinHex2 <a> <b> <c> <d> <t<sub>F</sub>>*****Description***

Place linear (in 6 or 8 dimensions) interpolated move into the coordinated motion buffer. This command is exactly the same as the [LinearHex](#) or [LinearHexEx](#) command above, except neither the beginning or ending point is specified and is assumed to be the same as the most recent [LinearHex](#), [LinearHexEx](#), [LinHex1](#), or LinHex2, command. This command can be used when there are more than one phases (ie Jerk, acceleration, constant velocity, etc. that occur along a single linear segment). See also [KMotion Coordinated Motion](#).

***Parameters***

See above.

***Example***

**LinHex2 0 0 3F800000 0 3F800000**

---

**LinHexEx1 <X<sub>1</sub>> <Y<sub>1</sub>> <Z<sub>1</sub>> <A<sub>1</sub>> <B<sub>1</sub>> <C<sub>1</sub>> <U<sub>1</sub>> <V<sub>1</sub>> <a> <b> <c> <d> <t<sub>F</sub>>*****Description***

Place linear (in 8 dimensions) interpolated move into the coordinated motion buffer. This command is exactly the same as the [LinearHexEx](#) command above, except the beginning point is not specified and is assumed to be the endpoint of the previous [LinearHexEx](#) or LinHexEx1 command. See also [KMotion Coordinated Motion](#).

***Parameters***

See above.

***Example***

**LinHexEx1 3F800000 3F800000 3F800000 3F800000 3F800000 3F800000 3F800000 0 0 3F800000 0 3F800000**

**LoadData <H> <N>****<B> <B> <B> <B> <B> ...*****Description***

Store data bytes into memory beginning at specified address for N bytes. The data must follow with up to N\_BYT<sub>E</sub>S\_PER\_LINE (64) bytes per line. This command is normally only used by the [COFF](#) loader. Since this command spans several lines, it may only be used programmatically in conjunction with a [KMotionLock](#) or [WaitToken](#) command so that it is not interrupted.

***Parameters*****<H>**

32-bit hexadecimal address

**<N>**

Number of bytes to follow and to be stored

**<B> <B> <B> <B> <B> ...**

Bytes to store. 2 hexadecimal digits per byte, separated with a space.

***Example*****LoadData 80030000 4****FF FF FF FF****LoadFlash<H> <N>****<B> <B> <B> <B> <B> ...*****Description***

Store data into FLASH image. Only by **KMotion** for downloading a new firmware version. Store data bytes into memory beginning at specified address for N bytes. The data must follow with up to N\_BYT<sub>E</sub>S\_PER\_LINE (64) bytes per line. This command is normally only used by the [COFF](#)

loader. Since this command spans several lines, it may only be used programmatically in conjunction with a [KMotionLock](#) or [WaitToken](#) command so that it is not interrupted.

### **Parameters**

**<H>**

32-bit hexadecimal address

**<N>**

Number of bytes to follow and to be stored

**<B> <B> <B> <B> <B> ...**

Bytes to store. 2 hexadecimal digits per byte, separated with a space.

### **Example**

**LoadFlash FF00 4**

**FF FF FF FF**

**MasterAxis<N>=<M>**

or

**MasterAxis<N>**

### **Description**

Sets or gets the axis **<M>** to which the current axis **<N>** is to be slaved. The current axis becomes a slave and will follow the motion of the specified Master Axis. More than one axis can be slaved to a single master axis if desired. When slaved, changes in the commanded destination of the master axis will be mirrored as changes in the slaved axis's destination however scaled by the [SlaveGain](#) (as specified in the Slave Axis). The SlaveGain may be negative if opposing motion is desired.

Setting the Master Axis value to -1 disables the Slave mode.

### **Parameters**

**<N>**

Selected Axis for command. Valid range 0 ... 7.

**<M>**

Master Axis or -1 to disable. Valid range -1 ... 7.

***Example (set axis 1 to follow axis 0)***

**MasterAxis1=0**

or

**MasterAxis**

---

**MaxErr<N>=<M>**

or

**MaxErr<N>**

***Description***

Set or get *Maximum Error* for axis (Limits magnitude of error entering PID).

See [Servo Flow Diagram](#) and [Step Response Screen](#) for more information.

***Parameters***

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Maximum Error. Valid range - any positive value. Set to a [large value](#) to disable.

***Example***

**MaxErr0=100.0**

or

**MaxErr0**

---

**MaxFollowingError<N>=<M>**

or

## MaxFollowingError<N>

### Description

Set or get the maximum allowed [following error](#) before [disabling](#) the axis.

### Parameters

<N>

Selected Axis for command. Valid range 0...7.

<M>

Maximum Following Error. Valid range - any positive value. Set to a [large value](#) to disable.

### Example

**MaxFollowingError0=100.0**

or

**MaxFollowingError0**

---

## MaxI<N> <M>

### Description

Set or get Maximum Integrator "wind up" for axis. Integrator saturates at the specified value.

See also [Servo Flow Diagram](#) and [Step Response Screen](#) for further information.

### Parameters

<N>

Selected Axis for command. Valid range 0...7.

<M>

Maximum Integrator value. Valid range - any positive value. Set to a [large value](#) to disable.

### Example

**MaxI0=100.0**

or

**MaxI0**

---

**MaxOutput<N>=<M>**

or

**MaxOutput<N>**

### ***Description***

Set or get Maximum Output for an axis. Limits magnitude of servo output. Output saturates at the specified value.

See also [Servo Flow Diagram](#) and [Step Response Screen](#) for further information.

### **Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Maximum output value. Valid range - any positive value. Set to a [large value](#) to disable.

### ***Example***

**MaxOutput0=100.0**

or

**MaxOutput**

---

**Move<N>=<M>**

### ***Description***

Move axis to absolute position. Axis should be already enabled. Uses [Vel](#), [Accel](#) and [Jerk](#) parameters for the axis to profile a motion from the current state to the specified position.

### **Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

new *position* in position units. Valid range - any.

### **Example**

**Move0=100.1**

---

**MoveAtVel<N>=<M> <V>**

### **Description**

Move axis to absolute position at the specified Velocity. Axis should be already enabled. Uses [Accel](#) and [Jerk](#) parameters for the axis to profile a motion from the current state to the specified position.

### **Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

new *position* in position units. Valid range - any.

**<V>**

Desired Velocity for the Motion. Valid range - any.

### **Example**

**MoveAtVel0=100.1 30.0**

---

**MoveAtVelAccel<N>=<D> <V><A>**

### **Description**

Move axis N to absolute coordinates D at the specified Velocity and Acceleration.

## Parameters

### <N>

Selected Axis for command. Valid range 0...7.

### <D>

Coordinates in position units. Valid range - any.

### <V>

Desired Velocity for the Motion. Valid range - any.

### <A>

Desired Acceleration for the Motion. Valid range - any.

## Example

MoveAtVelAccel0=100.1 30.0 2000.0

---

## MoveExp<N>=<D> <T>

## Description

Moves axis in an exponential manner toward the Destination using Time Constant T. The velocity of motion will be proportional to the distance from the Destination. The distance to the Destination will be reduced by 63% (1/e) every Time Constant, T. The Axis should be already enabled. Honors the Vel and Accel axis parameters.

## Parameters

### <N>

Selected Axis for command. Valid range 0...7.

### <D>

Destination in position units. Valid range - any.

**<T>**

Time Constant Tau in seconde. Valid range - any positive number.

***Example***

**MoveExp0=1000 0.1**

---

**MoveRel<N>=<M>*****Description***

Move axis relative to current destination. Same as [Move](#) command except specified motion is relative to current destination.

Axis should be already enabled. Uses [Vel](#), [Accel](#) and [Jerk](#) parameters for the axis to profile a motion from the current state to the specified position.

***Parameters*****<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Distance to move in position units. Valid range - any.

***Example***

**MoveRel0=100.1**

---

**MoveRelAtVel<N>=<M> <V>*****Description***

Move axis relative to current destination at the specified Velocity. Same as [MoveAtVel](#) command except specified motion is relative to current destination. Axis should be already enabled. Uses [Accel](#) and [Jerk](#) parameters for the axis to profile a motion from the current state to the specified position.

***Parameters***

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

new *position* in position units. Valid range - any.

**<V>**

Desired Velocity for the Motion. Valid range - any.

***Example***

**MoveRelAtVel0=100.1 30.0**

---

**MoveRelAtVelAccel<N>=<D> <V><A>*****Description***

Move axis N relative to current destination D at the specified Velocity and Acceleration.

***Parameters*****<N>**

Selected Axis for command. Valid range 0...7.

**<D>**

Coordinates in position units. Valid range - any.

**<V>**

Desired Velocity for the Motion. Valid range - any.

**<A>**

Desired Acceleration for the Motion. Valid range - any.

***Example***

**MoveAtVelAccel0=100.1 30.0 2000.0**

---

**MoveRelAtVelAccelSoft<N>=<D> <V><A>****Description**

Move axis N relative to current destination D at the specified Velocity and Acceleration. Limit to Soft Limit range

**Parameters****<N>**

Selected Axis for command. Valid range 0...7.

**<D>**

New *destination* in position units. Valid range - any.

**<V>**

Desired Velocity for the Motion. Valid range - any.

**<A>**

Desired Acceleration for the Motion. Valid range - any.

**Example**

MoveRelAtVelAccelSoft0=100.1 30.0 2000.0

---

**MoveXYZABC <X> <Y> <Z> <A> <B> <C>****Description**

Move the 6 axes defined to be X, Y, Z, A, B, C (each axis moves independently). The [defined coordinate system](#) determines which axes channels are commanded to move.

**Parameters****<X>**

Position to move x axis. Valid range - any.

**<Y>**

Position to move y axis. Valid range - any.

**<Z>**

Position to move z axis. Valid range - any.

**<A>**

Position to move a axis. Valid range - any.

**<B>**

Position to move b axis. Valid range - any.

**<C>**

Position to move c axis. Valid range - any.

***Example***

**MoveXYZABC 100.1 200.2 300.3 400.4 500.5 600.6**

---

**OpenBuf*****Description***

Clear and open the buffer for [coordinated motion](#).

***Parameters***

None

***Example***

**OpenBuf**

---

**OutputChan<M> <N>=<C>**

---

**or**

## OutputChan<M> <N>

### Description

Get or Set the first or second *Output Channel* of an axis. See description of this parameter on the [Configuration Screen](#).

### Parameters

<M>

Selected input channel. Valid range 0...1.

<N>

Selected Axis for command. Valid range 0...7.

<C>

Channel number to assign. Valid range 0...7.

**Example (set first output channel of axis 3 to 3)**

OutputChan03=3

---

## OutputGain<N>=<G>

or

## OutputGain<N>

### Description

Get or Set the *Output Gain* of an axis. For Axes of Step/Dir, CL Step Dir, or MicroStep output mode, the output motion can be scaled or reversed. Normally there is no need to use a value other than -1.0 or +1.0. For DAC Servo output mode the output signal (DAC) can be scaled or reversed. Again, normally there is no need to use a value other than -1.0 or +1.0. In other output modes the OutputGain value will have no effect.

### Parameters

<N>

Selected Axis for command. Valid range 0...7.

**<G>**

Gain value. Valid range any floating point value.

***Example***

**OutputGain0=-1.0**

or

**OutputGain0**

---

**OutputOffset<N>=<O>**

or

**OutputOffset<N>**

***Description***

Get or Set the *Output Offset* of an axis. For DAC Servo output mode the output (DAC) signal can be offset. The Output Offset is applied after any [Output Gain](#) value. The Output Offset can be used to reduce any DAC output offset or Amplifier input offset that may cause motor axis drift occurs when the DAC is commanded to zero (disabled). In other output modes the OutputGain value will have no effect.

***Parameters*****<N>**

Selected Axis for command. Valid range 0...7.

**<G>**

Gain value. Valid range any floating point value.

***Example***

**OutputGain0=-1.0**

or

**OutputGain0**

---

**OutputMode<N>=<M>**

or

## **OutputMode<N>**

### ***Description***

Set or get the position output mode for an axis. See description of this parameter on the [Configuration Screen](#).

Valid modes are (from PC\_DSP.h):

```
#define NO_OUTPUT_MODE 0
#define MICROSTEP_MODE 1
#define DC_SERVO_MODE 2
#define BRUSHLESS_3PH_MODE 3
#define BRUSHLESS_4PH_MODE 4
#define DAC_SERVO_MODE 5
#define STEP_DIR_MODE 6
#define CL_STEP_DIR_MODE 7
#define CL_MICROSTEP_MODE 8
```

### ***Parameters***

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Mode. Valid range 1...4

### ***Example***

**SetOutputMode0=1**

---

**P<N>=<M>**

or

**P<N>**

### ***Description***

Get or Set [PID](#) Proportional Gain.

### **Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Proportional Gain value. The units of the derivative gain are in Output Units/Position Units.

### **Example**

**P0=10.0**

---

**Pos<N>=<P>**

or

**Pos<N>**

### **Description**

Set or get the measured [position](#) of an axis. Note setting the current position may effect the commutation of any motors based on the position (an adjustment in the [commutation offset](#) may be required).

### **Parameters**

**<N>**

Selected Axis for command. Valid range 0...7.

**<P>**

value to be stored into the current position. units are position units. Valid range - any.

### **Example**

**Pos0=100.0**

---

**ProgFlashImage**

### **Description**

Program entire FLASH image, downloaded using [LoadFlash](#) commands, to FLASH Memory.

**Parameters**

None

**Example**

ProgFlashImage

---

**PWM<N>=<M>**

**Description**

Set PWM channel to [locked anti-phase mode](#) and to specified value.

See [PWM Description](#) and [Analog Status Screen](#).

**Parameters****<N>**

PWM channel number. Valid range 0...7

**<M>**

PWM value. Valid range -255...255.

**Example**

PWM0=-99

---

**PWMC<N>=<M>**

**Description**

Set PWM channel to Current Mode and to specified value. PWM Channel will operate in closed loop current mode.

See [Analog Status Screen](#).

**Parameters****<N>**

PWM channel number. Valid range 0...7

**<M>**

PWM value. Valid range -1000...1000. 1 count = 35 Amps/1024 = 34.2ma

***Example*****PWM0=-99**

---

**PWMR<N>=<M>*****Description***

Set PWM channel to [recirculate mode](#) and to specified value.

See [PWM Description](#) and [Analog Status Screen](#).

***Parameters*****<N>**

PWM channel number. Valid range 0...7

**<M>**

PWM value. Valid range -511...511.

***Example*****PWMR0=-99**

---

**ReadBit<N>*****Description***

Displays whether an actual hardware I/O bit N or Virtual IO bit is high (1) or low (0). A bit defined as an output (See [SetBitDirection](#)) may also be read back.

***Parameters*****<N>**

Bit number to read. Accepted range - 0...2047

***Example*****ReadBit0**

---

**Reboot!*****Description***

Causes complete power up reset and re-boot from flash memory.

### **Parameters**

None

### **Example**

**Reboot!**

---

## **SetBit<N>**

### **Description**

Sets an actual hardware I/O bit N or Virtual I/O bit to high (1).

### **Parameters**

**<N>**

Bit number to set. Accepted range 0...2047

### **Example**

**SetBit0**

---

## **SetBitBuf<N>**

### **Description**

Inserts into the [coordinated move buffer](#) a command to set an I/O bit (actual I/O bits must be defined as an output, see [SetBitDirection](#))

### **Parameters**

**<N>**

Bit number to set. Valid range 0...63

### **Example**

**SetBitBuf0**

---

## **SetBitDirection<N>=<M>**

### **Description**

Defines the direction of an I/O bit to be an input or output. Depending on the type of I/O, it may not be possible to change direction as some I/O bits are strictly inputs, and some are strictly outputs.

See also [Digital I/O Screen](#).

### **Parameters**

#### **<N>**

Bit number to assign. Accepted range 0...2047

#### **<M>**

Direction 0 = input, 1 = output

### **Example**

**SetBitDirection0=1**

## **SetFRO <F>**

### **Description**

Sets Hardware FRO (Feed Rate Override) in KFLOP which is the rate that the Coordinated Motion Buffer is executed. A value of 1.0 = Normal Feed Rate = real time = an advance of 90us of time every 90us Servo Sample Period.

A negative FRO value will cause the Coordinated Motion Buffer to execute in reverse up until the beginning or until the point where Coordinated Motion Buffer data has been lost due to buffer wrapping (MAX\_SEGMENTS is currently ~35,000 segments). When approaching the point where previous data was lost, the FRO will be automatically reduced to zero in order to avoid an abrupt stop. This will not occur (and should not be necessary) when approaching the actual beginning of the buffer because normal acceleration from a stop should exist. In this case Time will stop abruptly when the beginning of the buffer is reached.

In order to avoid an instantaneous change in velocity the FRO will be ramped from the current rate to the specified rate. This command uses a default ramp rate that has been determined based on the Max Allowed Velocities, Accelerations, and Jerks of all the currently defined Coordinate Motion System Axes Channels. In order to specify a different rate the [SetFROwRate](#) command may be used.

This command will not alter the rate of execution if the FeedHold mechanism is currently in effect. See [StopImmediate](#). However the specified speed will be saved so that if FeedHold is eventually released, the rate will resume to this specified speed. To change the FRO while in FeedHold use the [SetFROTemp](#) or [SetFROwRateTemp](#) commands instead. Those commands were intended to be used while in Feed Hold and will not alter the rate that will be resumed after Feed Hold is released.

**Parameters****<F>**

Desired FRO Value. 1.0 corresponds to normal Real Time, 0.0 corresponds to fully stopped, negative values drive time in reverse. Valid range -100...+100

**Example****SetFRO 1.2****SetFROTemp <F>****Description**

Sets Hardware FRO (Feed Rate Override) in KFLOP which is the rate that the Coordinated Motion Buffer is executed. A value of 1.0 = Normal Feed Rate = real time = an advance of 90us of time every 90us Servo Sample Period.

This command is intended for temporary FRO changes while in Feed Hold.

See [SetFRO](#) for additional Information.

**Parameters****<F>**

Desired FRO Value. 1.0 corresponds to normal Real Time, 0.0 corresponds to fully stopped, negative values drive time in reverse. Valid range -100...+100

**Example****SetFROTemp -0.2****SetFROwRate <F> <R>****Description**

Sets Hardware FRO (Feed Rate Override) in KFLOP which is the rate that the Coordinated Motion Buffer is executed. A value of 1.0 = Normal Feed Rate = real time = an advance of 90us of time every 90us Servo Sample Period. This command functions the same as the command SetFRO with the exception that the rate at which the FRO will be ramped to the new FRO may be controlled. The ramp rate (rate-of-change-of-rate-of-time) to be used is determined from a user

supplied Time Parameter. The Time to ramp from FRO=0. to FRO=1.0. See [SetFRO](#) for more information.

### Parameters

#### <F>

Desired FRO Value. 1.0 corresponds to normal Real Time, 0.0 corresponds to fully stopped, negative values drive time in reverse. Valid range -100...+100

#### <R>

Time to ramp from FRO=0.0 to FRO=1.0 Valid range any positive number.

### Example

**SetFROwRate 1.2 0.5**

---

## SetFROwRateTemp <F> <R>

### Description

Sets Hardware FRO (Feed Rate Override) in KFLOP which is the rate that the Coordinated Motion Buffer is executed. A value of 1.0 = Normal Feed Rate = real time = an advance of 90us of time every 90us Servo Sample Period. This command functions the same as the command SetFROTemp with the exception that the rate at which the FRO will be ramped to the new FRO may be controlled. The ramp rate (rate-of-change-of-rate-of-time) to be used is determined from a user supplied Time Parameter. The Time to ramp from FRO=0. to FRO=1.0.

This command is intended for temporary FRO changes while in Feed Hold.

See [SetFRO](#) for additional Information.

### Parameters

#### <F>

Desired FRO Value. 1.0 corresponds to normal Real Time, 0.0 corresponds to fully stopped, negative values drive time in reverse. Valid range -100...+100

#### <R>

Time to ramp from FRO=0.0 to FRO=1.0 Valid range any positive number.

### Example

**SetFROwRateTemp -0.2 0.5**

**SetGatherDec <N> <M>****Description**

Writes a single word to the [Gather Buffer](#) at the specified offset. A single 32-bit value specified as a signed decimal integer number will be stored.

The corresponding value may be accessed by a **KMotion** user program using the pointer : **gather\_buffer**. This pointer should be cast as an integer pointer in order to reference values as integers and to use the same index.

See also [GetGatherDec](#), [GetGatherHex](#), [SetGatherHex](#)

**Parameters****<N>**

Offset into gather buffer, specified as a decimal offset of 32 bit words. Valid range 0...1999999

**<M>**

Value to be stored. Valid range -2147483648...2147483647

**Example**

**SetGatherDec 1000 32767**

**SetGatherHex<N>****<M>**

**<H> <H> <H> ...**

**Description**

Writes a *multiple* words to the [Gather Buffer](#) beginning at the specified offset. 32-bit values specified as a unsigned hexadecimal numbers must follow with 8 words per line separated with spaces. Since this command spans several lines, it may only be used programmatically in conjunction with a [KMotionLock](#) or [WaitToken](#) command so that it is not interrupted.

The corresponding values may be accessed by a **KMotion** user program using the pointer : **gather\_buffer**. This pointer should be cast as an integer pointer in order to reference values as integers and to use the same index.

See also [GetGatherDec](#), [GetGatherHex](#), [SetGatherDec](#)

### **Parameters**

**<N>**

Offset into gather buffer, specified as a decimal offset of 32 bit words. Valid range 0...1999999

**<M>**

Number of value to be stored, specified as a decimal number. Valid range 0...19999999

**<H> <H> <H> ...**

Values to be stored. Specified as unsigned Hexadecimal values. Valid range 0...FFFFFFF.

### **Example**

**SetGatherHex 0 3**

FFFFFFFFFF FFFFFFFFFFF FFFFFFFFFFF

## **SetPersistDec <O> <D>**

### **Description**

Write a single word into the Persistent *UserData* Array. Persistent *UserData* Array is a general purpose array of 100 32-bit words that may be used as commands, parameters, or flags between any host applications or **KMotion** user programs. The array resides in a *persistent* memory area, so that if a value is set as a parameter and the User Programs are *flashed*, the value will persist permanently.

The corresponding value may be accessed by a **KMotion** user program as the integer variable : persist.UserData[offset].

See also [GetPersistDec](#), [GetPersistHex](#), [SetPersistHex](#)

### **Parameters**

**<O>**

Offset into the user data array specified as a decimal number. Valid Range 0 ... 99.

**<D>**

Value to be written to the array. Specified a signed decimal number. Valid Range -2147483648 ... 2147483647

***Example*****SetPersistDec 10 32767****SetPersistHex <O> <H>*****Description***

Write a single word into the Persistent *UserData* Array. Persistent *UserData* Array is a general purpose array of 100 32-bit words that may be used as commands, parameters, or flags between any host applications or **KMotion** user programs. The array resides in a *persistent* memory area, so that if a value is set as a parameter and the User Programs are *flashed*, the value will persist permanently.

The corresponding value may be accessed by a KMotion user program as the integer variable : persist.UserData[offset].

See also [GetPersistDec](#), [GetPersistHex](#), [SetPersistDec](#).

***Parameters*****<O>**

Offset into the user data array specified as a decimal number. Valid range 0 ... 99.

**<H>**

Value to be written to the array. Specified an unsigned hexadecimal number. Valid range 0...FFFFFFF

***Example*****SetPersistHex 10 FFFFFFFF****SetRapidFRO <F>*****Description***

Sets Hardware RFRO (Rapid Feed Rate Override) in KFLOP which is the rate that the Coordinated Motion Buffer is executed. A value of 1.0 = Normal Feed Rate = real time = an advance of 90us of time every 90us Servo Sample Period.

Note: KFLOP Maintain separate Rate Overides for Rapid motion vs normal Feed Motion. Commands ([BegRapidBuf](#) and [EndRapidBuf](#)) inserted into the Coordinated Motion Buffer determine what type of motion is currently in progress and which Override is to be used.

A negative RFRO value will cause the Coordinated Motion Buffer to execute in reverse up until the beginning or until the point where Coordinated Motion Buffer data has been lost due to buffer wrapping (MAX\_SEGMENTS is currently ~35,000 segments). When approaching the point where previous data was lost, the RFRO will be automatically reduced to zero in order to avoid an abrupt stop. This will not occur (and should not be necessary) when approaching the actual beginning of the buffer because normal acceleration from a stop should exist. In this case Time will stop abruptly when the beginning of the buffer is reached.

In order to avoid an instantaneous change in velocity the RFRO will be ramped from the current rate to the specified rate. This command uses a default ramp rate that has been determined based on the Max Allowed Velocities, Accelerations, and Jerks of all the currently defined Coordinate Motion System Axes Channels. In order to specify a different rate the [SetRapidFROwRate](#) command may be used.

This command will not alter the rate of execution if the FeedHold mechanism is currently in effect. See [StopImmediate](#). However the specified speed will be saved so that if FeedHold is eventually released, the rate will resume to this specified speed. To change the FRO while in FeedHold use the [SetFROTemp](#) or [SetFROwRateTemp](#) commands instead. Those commands were intended to be used while in Feed Hold and will not alter the rate that will be resumed after Feed Hold is released.

### **Parameters**

#### **<F>**

Desired RFRO Value. 1.0 corresponds to normal Real Time, 0.0 corresponds to fully stopped, negative values drive time in reverse. Valid range -100...+100

### **Example**

#### **SetRapidFRO 1.2**

---

#### **SetRapidFROwRate <F> <R>**

### **Description**

Sets Hardware RFRO (Rapid Feed Rate Override) in KFLOP which is the rate that the Coordinated Motion Buffer is executed. A value of 1.0 = Normal Feed Rate = real time = an advance of 90us of time every 90us Servo Sample Period. This command functions the same as the command SetRapidFRO with the exception that the rate at which the RFRO will be ramped to the new RFRO may be controlled. The ramp rate (rate-of-change-of-rate-of-time) to be used is determined from a user supplied Time Parameter. The Time to ramp from FRO=0. to FRO=1.0. See [SetRapidFRO](#) for more information.

Note: KFLOP Maintain separate Rate Overrides for Rapid motion vs normal Feed Motion. Commands ([BegRapidBuf](#) and [EndRapidBuf](#)) inserted into the Coordinated Motion Buffer determine what type of motion is currently in progress and which Override is to be used.

### **Parameters**

#### **<F>**

Desired RFRO Value. 1.0 corresponds to normal Real Time, 0.0 corresponds to fully stopped, negative values drive time in reverse. Valid range -100...+100

#### **<R>**

Time to ramp from RFRO=0.0 to RFRO=1.0 Valid range any positive number.

### **Example**

**SetRapidFROwRate 1.2 0.5**

## **SetStartupThread<N> <M>**

### **Description**

Defines whether a user thread is to be launched on power up.

### **Parameters**

#### **<N>**

Selected User Thread. Valid range 1...7

#### **<M>**

Mode : 1=start on boot, 0=do not start on boot.

### **Example**

**SetStartupThread0 1**

## **SetStateBit<N>=<M>**

### **Description**

Sets the state of an actual hardware I/O bit to either low (0) or high (1). Actual I/O bits must be defined as an output, see [SetBitDirection](#).

**Parameters****<N>**

Bit number to set. Accepted range 0...2047

**<M>**

State. Valid range 0...1

**Example****SetStateBit0=1****SetStateBitBuf<N>=<M>****Description**

Inserts into the [coordinated move buffer](#) a command to set the state of an I/O bit (actual IO bits must be defined as an output, see [SetBitDirection](#)).

**Parameters****<N>**

Bit number to set. Accepted range 0...2047

**<M>**

State. Valid range 0...1

**Example****SetBitBuf0****SetStateBitBuf0=1****SlaveGain<N>=<S>****or****SlaveGain<N>****Description**

Sets or gets the Slave Gain for the axis. See also [MasterAxis](#) for more information

**Parameters**

**<N>**

Selected Axis for command. Valid range 0 ... 7.

**<S>**

Slave Gain. Any floating point value positive or negative.

***Example***

**SlaveGain0=-1.0**

or

**SlaveGain0**

**SoftLimitNeg<N>=<M>**

or

**SoftLimitPos<N>**

***Description***

Command to set or display the Negative Software Limit of Travel. Soft Limits will prevent motion in the same manner as a Hardware Limit with the Stop Movement Action Selected. This occurs regardless of the Action Type Selected for the Hardware Limit Switches. To disable Soft Limits set them to a huge range which could never occur. Soft Limits prevent motion within KFLOP when Jogging, moving and so forth. They also are uploaded by Applications such as KMotionCNC and used to prevent motion during Trajectory Planning. The Negative Soft Limit is used to prevent motion beyond a limit in the negative direction. The Negative Soft Limit does not necessarily need to be negative. See also [SoftLimitPos](#).

**Parameters****<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Maximum Negative Limit. Valid range - any value. Set to a [large value](#) to disable.

***Example***

**SoftLimitNeg0=-1000000.0**

or  
**SoftLimitNeg0**

---

**SoftLimitPos<N>=<M>**

or

**SoftLimitPos<N>*****Description***

Command to set or display the Positive Software Limit of Travel. Soft Limits will prevent motion in the same manner as a Hardware Limit with the Stop Movement Action Selected. This occurs regardless of the Action Type Selected for the Hardware Limit Switches. To disable Soft Limits set them to a huge range which could never occur. Soft Limits prevent motion within KFLOP when Jogging, moving and so forth. They also are uploaded by Applications such as KMotionCNC and used to prevent motion during Trajectory Planning. The Positive Soft Limit is used to prevent motion beyond a limit in the positive direction. The Positive Soft Limit does not necessarily need to be positive. See also [SoftLimitNeg](#).

***Parameters*****<N>**

Selected Axis for command. Valid range 0...7.

**<M>**

Maximum Positive Limit. Valid range - any value. Set to a [large value](#) to disable.

***Example***

**SoftLimitPos0=1000000.0**

or  
**SoftLimitPos0**

---

**StepperAmplitude<N>=<M>**

or

## **StepperAmplitude<N>**

### ***Description***

Set or get the nominal output magnitude used for axis if in MicroStepping [Output Mode](#) to the specified value. This will be the output amplitude when stopped or moving slowly. If [Lead Compensation](#) is used, the amplitude while moving may be higher.

### **Parameters**

#### **<N>**

Selected Axis for command. Valid range 0...7.

#### **<M>**

PWM Stepper Amplitude. Valid range 0...255

### ***Example***

**StepperAmplitude0=250**

## **StopImmediate<M>**

### ***Description***

Controls the Feedhold Mechanism for the set of coordinated motion Axes. This command can be used to feedhold (bring to an immediate stop) the set of axes, Resume from a feedhold, or clear the feedhold state. This command can stop the set of axes regardless of whether the current motion in progress is due to coordinated motion (Interpolated Linear or Arc) or independent axes motions (Rapids). The current state can be obtained using the [GetStopState](#) command.

### **Parameters**

#### **<M>**

Mode

- 0 - Stops the axes motion (equivalent to User C Program function StopCoordinatedMotion)
- 1 - Resumes the axes motion (equivalent to User C Program function ResumeCoordinatedMotion)
- 2 - Clears the Feed hold state (equivalent to User C Program function ClearStopImmediately)

### ***Example***

**StopImmediate0**

---

## TrigThread <S>

### Description

Triggers a coordinated motion threading operation. The coordinated motion path in the coordinated motion buffer begins execution synchronized with the Spindle motion. The Speed specified will be used as the baseline speed such that if the actual spindle speed is equal to the base speed, then Pseudo Time will progress the same as real time. Otherwise Pseudo time will be adjusted to match the spindle motion

See also: [ConfigSpindle](#) and [GetSpindleRPS](#)

### Parameters

<S>

Base Spindle Speed in revs per second. Range: Any floating point value.

### Example

TrigThread 10.0

---

Vel<N>=<V>

or

Vel <N>

### Description

Get or Set the max velocity for independent moves.

### Parameters

<N>

Selected Axis for command. Valid range 0...7.

<V>

The max velocity. Units are in *Position units* per sec

### Example

Vel0=100.0

---

## Version

### ***Description***

Display DSP Firmware Version and Build date in the form:.

KMotion 2.22 Build 22:26:57 Feb 16 2005

Note it is important that when C Programs are compiled and linked, they are linked to a firmware file, DSP\_KMotion.out, that matches the firmware in the KMotion where they will execute.

### ***Parameters***

None

### ***Example***

#### **Version**

---

## WaitBitBuf<N>

### ***Description***

Inserts into the coordinated move buffer a command to wait for an I/O bit to be at a high level. This command is useful for synchronizing motion to external events without any PC delays.

This command can be inserted into the Coordinated motion buffer from KMotionCNC GCode using the special comment command format of:

(BUF,WaitBitBuf46)

### ***Parameters***

#### **<N>**

Bit number to wait to be high. Accepted range 0...2047

### ***Example***

#### **WaitBitBuf46**

---

## WaitNotBitBuf<N>

## Description

Inserts into the coordinated move buffer a command to wait for an IO bit to be at a low level. This command is useful for synchronizing motion to external events without any PC delays.

This command can be inserted into the Coordinated motion buffer from KMotionCNC GCode using the special comment command format of:

(BUF,WaitNotBitBuf46)

## Parameters

<N>

Bit number to wait to be low. Valid range 0...2047

## Example

WaitNotBitBuf46

---

Zero<N>

## Description

Clear the measured position of axis. Note for an axis that uses the [Position](#) to perform brushless motor commutation, the [commutation offset](#) may be required to be adjusted whenever the position measurement is changed.

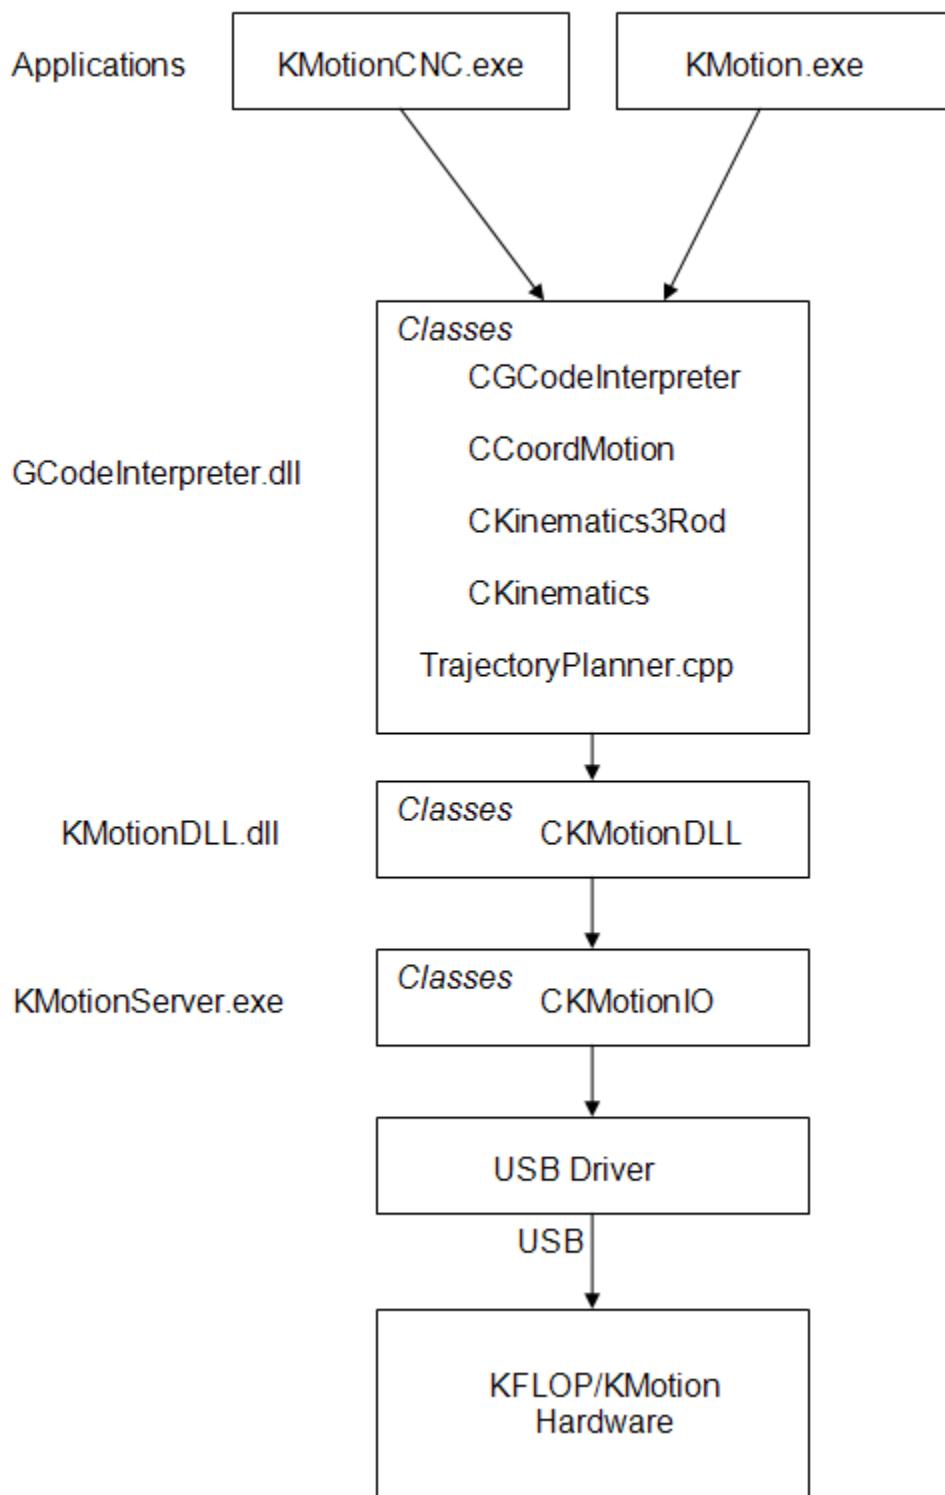

## Parameters

<N>

Selected Axis for command. Valid range 0...7.

## Example

Zero0

**KFLOP/KMotion Interface Libraries**

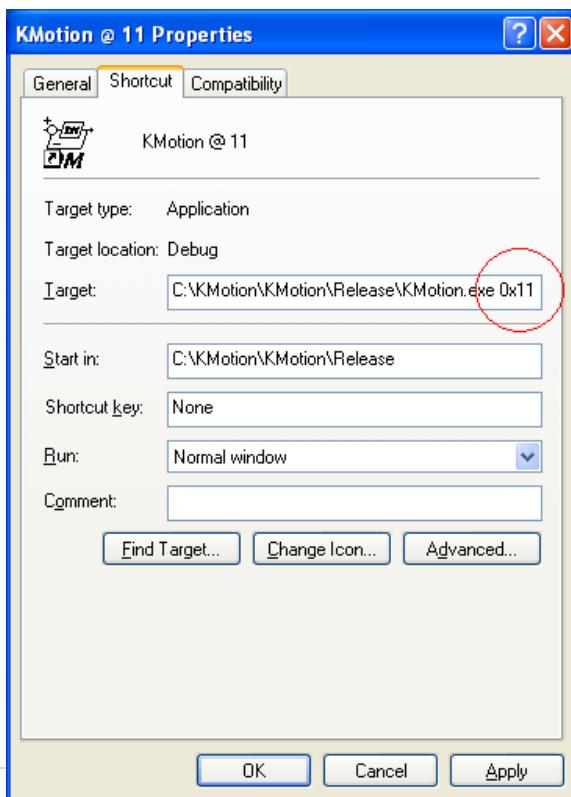

## Using Multiple KMotion Boards

The **KMotion** Driver Library allows multiple PC processes (applications), each running multiple threads of execution, to communicate with multiple **KMotion** boards simultaneously. Each **KMotion** board is identified by a USB *location identifier* where it is connected. A USB location identifier is a 32 bit integer. USB devices are arranged in a tree structure of hubs and nodes. Each hexadecimal digit of the USB location specifies a branch in the tree structure. For the purposes of the **KMotion** Driver Library, a USB location identifier may simply be considered a unique integer that will remain the same as long as the structure of the USB tree is not altered. Adding or removing USB devices will not change the location of a connected **KMotion** board.

Selecting the USB Locations menu of the **KMotion** Setup and Tuning application, will display a list of all currently connected **KMotion** boards. The Checkmark indicates which board the application is currently communicating with. To switch to a different board, select the USB location from the list.

When launching the **KMotion** Setup and Tuning application, a command line parameter may be specified to connect to a specific USB location (see below on how to setup a shortcut to connect to a specific location). Multiple shortcuts may be setup to connect to individual boards.

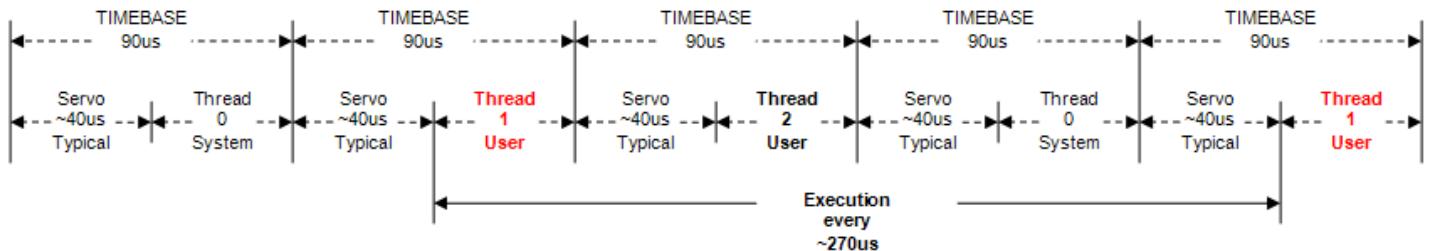

The **KMotion** Driver Library has a function to list the USB locations of all currently connected **KMotion** boards. See:

```
int ListLocations(int *nlocations, int *list);
```

When making **KMotion** Driver Library function calls specify the USB *location identifier* of the desired board as the board parameter shown in the example below. Specifying a board value of 0 may be used if there is only one board in a particular system. This will result in a connection to the first available board.

```
int CKMotionDLL::WriteLineReadLine(int board, const char *s, char *response)
```

## KMotion/KFlop Preemptive Multitasking

KMotion/KFlop uses a simple method of preemptive multitasking (multiple programs or "Threads" running at the same time). Each Thread consists of an area of memory where a program can be loaded, A CPU Stack for that program, and a potential time slice of the CPU. User Programs (Threads) and the System Thread context switch every Servo Interrupt and sequence in a round robin order.

The main thing to understand is that two programs that ever need to be running at the same time need to be assigned to different threads. The KFLOP system Thread runs all the time in Thread #0. So Thread #0 may never be used. In a typical KMotionCNC system the Init.c program is usually assigned to thread #1 and runs forever. If other UserButtons (or MCodes) run C Programs that do something and terminate (Exec/Wait option) then these might all be assigned to use Thread#2. If your programs run for a longer time where a 3rd or 4th program might be Launched so they all overlap in time, then they must all be assigned to different Threads.

Most Applications have a Red Stop Button that stops all or most Threads from executing. For example KMotion.exe stops all User Threads. KMotionCNC stops all User Threads except Thread #1 so any critical monitoring program might be placed in Thread #1 in order to continue execution after an Emergency Stop.

The above example shows a case where two User Threads are currently active.

The C function WaitNextTimeSlice() can be used to wait until the next context switch occurs and return immediately at the beginning of the next time slice. This can assure that the User Program can execute for a few microseconds without being interrupted and at a very stable rate (with a few microseconds of jitter).

The time period between executions of each user thread is a function of the number of active User Threads:

$$\text{Period} = (\# \text{ User Threads} + 1) * \text{TIMEBASE}$$

## KFLOP - RS232

KFLOP contains a UART that can allow KFLOP User C Programs to perform serial communication with other 3rd party devices.

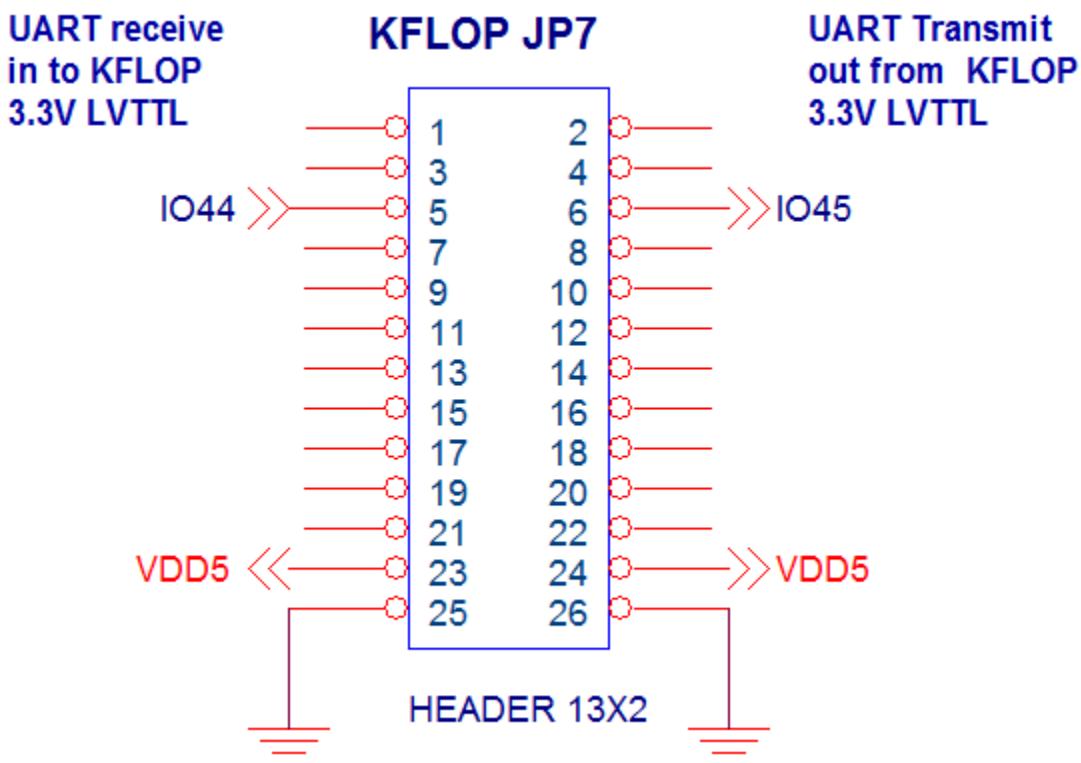

KFLOP itself contains the serial communication UART but does not have the circuitry to drive or receive the signals at the +3 to 25V to -3 to -25V voltages levels specified by the RS232 standard. The transmit and receive signals to/from KFLOP are 3.3V LVTTL logic signals. Where a low logic level (<0.4V) represents the RS232 Space Level (>+3V) and a high logic level represents the RS232 Mark Level (<-3V).

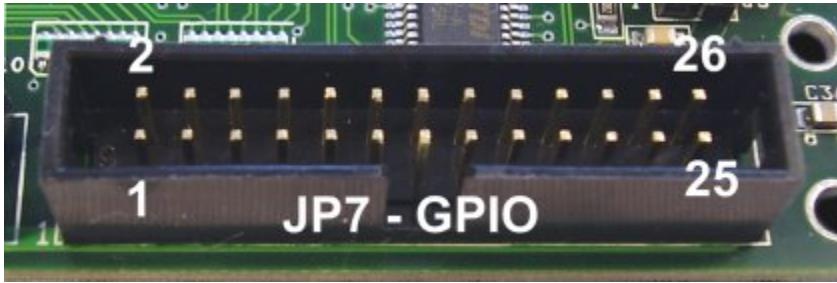

***Note that the signals that the signals coming directly from KFLOP are not RS232 compatible. Connecting KFLOP inputs directly to RS232 is likely to cause damage.***

Some serial devices may be compatible with 3.3V logic. Also many 3rd party converters are available. A Internet search found this one (we haven't tested it).

<http://www.commfront.com/TTL-RS232-RS485-Serial-Converters/RS232-TTL3.3V-Converter.htm>

Our Kanalog board has a LVTTL to converter on board (see next section below).

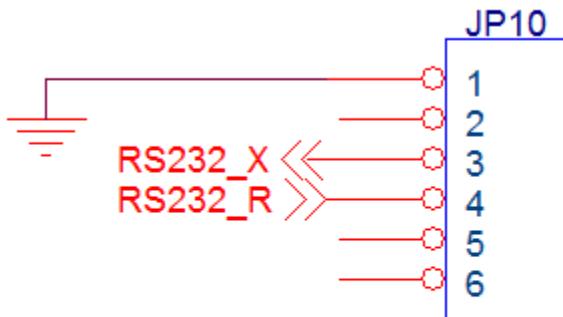

## KFLOP + Kanalog - RS232

Kanalog contains circuitry to convert the KFLOP UART logic levels to standard RS232 voltage levels. The RS232 signals are accessible from JP10 which is a standard RJ12 phone jack.

The pinout is shown below. The pinout is designed to be 1:1 compatible with certain PLC devices. Note that a phone cable with all 6 wires populated is required in order to make the pin 1 ground connection.

RJ12 TYCO 5555165-1

## KFLOP UART Software

The KFLOP FPGA implements a programmable baud rate UART with double buffering of 1 character on transmit and receive. Currently a KFLOP User C program must be used to make use of the UART. It is up to the User to program whatever is necessary to control any specific device.

KFlop User Programs with 1 active thread execute every 180us. (See [here](#) for more info). This allows rates up to 38400 baud without loss if a character is read every time slice (10 bits at 38400Hz = 260us). Data transmitted and received is always 8 bits. If parity is required it should be handled by the User C program.

To set the baud rate write a defined 8-bit baud rate divisor to an FPGA Register (RS232\_BAUD\_REG )

To transmit a character an 8-bit character is written to an FPGA register (RS232\_DATA).

To receive a character read an 8-bit value from an FPGA register (RS232\_DATA )

A status register (RS232\_STATUS) provides 2 bits of status that can be used to determine if a character has been received (RS232\_DATA\_READY) and if it is possible to transmit a character (RS232\_TRANSMIT\_FULL)

The following definitions have been added to the KMotionDef.h file.

```
//RS232 FPGA Register Definitions

#define RS232_STATUS 0xc1 // Status Reg Address
#define RS232_DATA 0xc0 // 8 bit data read/write reg address
#define RS232_DATA_READY 0x01 // Data ready to read status mask
#define RS232_TRANSMIT_FULL 0x02// Transmit buffer full status mask

#define RS232_BAUD_REG 0xc1 // Set Baud rate 8-bit divisor Reg Address
#define RS232_BAUD_115200 ((16666666/115200/16)-1)// 8-bit divisor value
to set 115200 baud
#define RS232_BAUD_57600 ((16666666/57600/16)-1) // 8-bit divisor value
to set 57600 baud
#define RS232_BAUD_38400 ((16666666/38400/16)-1) // 8-bit divisor value
to set 38400 baud
#define RS232_BAUD_19200 ((16666666/19200/16)-1) // 8-bit divisor value
to set 19200 baud
#define RS232_BAUD_9600 ((16666666/9600/16)-1) // 8-bit divisor value to
set 9600 baud
#define RS232_BAUD_4800 ((16666666/4800/16)-1) // 8-bit divisor value to
set 4800 baud
```

Note if KFLOP is to be used without Kanalog the UART IO pins must be activated by executing the following line of code one time:

```
FPGA(KAN_TRIG_REG)=2;
```

***Note the techniques shown below may be used but a new simpler and buffered method is now available. See the \C Programs\RS232\BufferedRS232.c example***

### **Transmit Example (RS232Send.c example)**

```
#include "KMotionDef.h"

void SendChar(char c)
{
while (FPGA(RS232_STATUS) & RS232_TRANSMIT_FULL) ;
FPGA(RS232_DATA) = c;
}
```

```

main()
{
int i;
SetBitDirection(45,1);
FPGA(RS232_BAUD_REG) = RS232_BAUD_38400;
// FPGA(KAN_TRIG_REG) = 1; // enable Kanalog to get RS232 working
for (i=0;i<100;i++)
{
SendChar('A');
}
}

```

### ***Receive Example (RS232Read.c example)***

```

#include "KMotionDef.h"

void ReceiveChar()
{
// wait for data in buffer
while ((FPGA(RS232_STATUS) & 1)==0);
return FPGA(RS232_DATA);
}

main()
{
SetBitDirection(45,1);
FPGA(RS232_BAUD_REG) = RS232_BAUD_38400;
// FPGA(KAN_TRIG_REG) = 1; // enable Kanalog to get RS232 working
for (;;)
{
while ((FPGA(RS232_STATUS) & RS232_DATA_READY) == 0) ;
printf("%X\n",ReceiveChar());
}
}

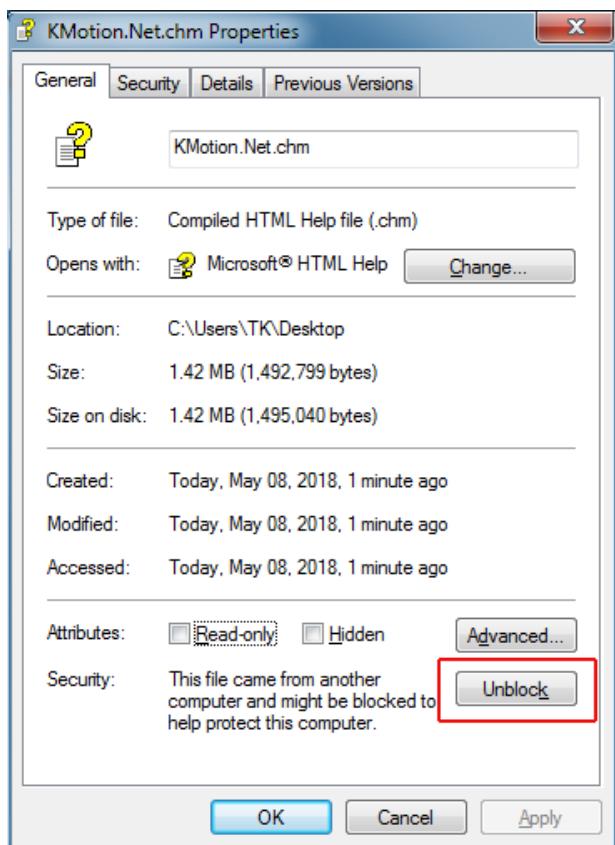

```

## .NET Interface

Dynomotion's Motion Libraries provide a .NET interface. The .NET interface allows all the functionality of the KMotion Libraries to be imported and made accessible to your application with a simple reference to KMotion\_dotNet.dll. .NET is a standard that works with many different Languages including Visual C#, Visual Basic, Visual C++, IronPython, LabView, and many others. Once the reference is included in the project all the classes, member functions, variable, and data types are accessible. Most languages will provide intellisense and auto complete for all the imported objects once a reference is established.

The functionality exposed by the KMotion .NET interfaces is documented in a Help file. This documentation is available in two formats. As an installed Windows Help file (KMotion\_dotNet.dll) or as [on-line pages](#) view-able with a browser. The Installed Windows Help file is installed with KMotion at <installed>\KMotion\_dotNet\Docs\Help\KMotion.Net.chm

You can also download the [.NET Interface](#) Windows Help from our website. You will need to save the file, then right-mouse-click it, and select “Properties” and “Unblock”:

**D** (Tool)

**O** Subroutine Label

#### Comments:

(Simple Comment)

(MSG,OK

toContinue?)

## Zero/Set Origin

Allows zeroing or setting the respective axis. This is accomplished by adjusting the Global Offsets (G52/G92) or by adjusting the currently selected Fixture Offset. Which offset is adjusted is determined by the Tool Setup Parameter described [here](#). The original Raw Machine Coordinates will remain unchanged, so the effect of these operations will only be apparent if displaying Machine Coordinates is de-selected, see below. For further information see [system offsets](#).

## Coordinate System Origin

**Machine Coord** When checked, the displayed position is the current tool position in Raw Machine Coordinates (G53 without any Global offset (G92) or Fixture Offset (G54+). Machine coordinates are relative to the fixed machine home position.

Unchecked displays the normal GCode Coordinate relative to the "floating" origin which may be moved by changing either the global offset (G92) and/or a Fixture Offset.

## Coordinate System Units / Mode

Displays the current mode of the G code interpreter.

**G20** selects English Inch units

**G21** selects Metric mm units

**G90** selects Absolute Coordinates

**G91** selects Relative Coordinates

(CMD,EnableAxis0)  
(BUF,SetBitBuf29)

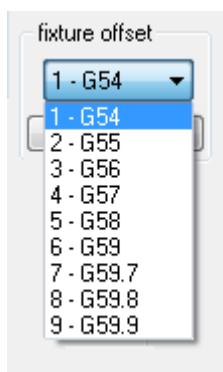

## More GCodes

### Keyboard Hot Keys

**ESC - Stop**  
**F2 - KeyJog on/off**  
**F3 - FeedHold**  
**F5 - Run/Halt**  
**F9 - Spindle On**  
**CW**  
**F10 - Spindle On**  
**CCW**  
**F11 - Spindle Off**

**KeyJog Mode**  
*(shift=fast)*  
*(ctrl=step)*  
**x y - Arrow Keys**  
**z - page up/down**  
**A - num - +**

### Fixture Offset

Displays and allows changing of the current Fixture Offset. KMotionCNC supports 9 Fixture offsets. Each Fixture may be programmed to introduce an arbitrary x,y,z,a offset. Use the **G10L2Pn** command to set the offset associated with the fixture #n. An example might be:

**G10 L2 P3 X10.0 Y20.0 Z30.0** which sets Fixture Offset #3 to (10,20,30)

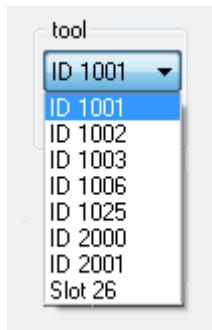

Executing the command **G56** (or by selecting 3 - G56 in the drop down list) will cause Fixture offset #3 to be in use in subsequent commands until a different Fixture is selected. (See also - [G Code Offsets](#)).

The “set” button can be used to automatically compute and change the current fixture offset so that the current position becomes the new origin.

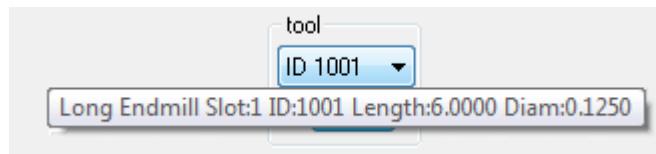

The “edit” button can be used to view, change, or save the fixture offsets. See [EditFixtureOffsets](#).

### Tool

Displays and allows changing of the currently selected Tool. KMotionCNC supports up to 99 tool definitions. GCode selects tools using several different commands for different purposes. The value displayed here is the value selected by the **T** command, which is the tool to be loaded into the spindle by a automatic tool changer. The T command is normally followed by a M6 command that receives the tool number and physically loads the tool. Selecting a tool in the the dropdown list will effectively cause a T#M6 command to be executed, where # is the selected tool number. Tools can be selected by either 4 digitID or 2 digit Slot numbers. The Dropdown displays the available Tools defined in the tool table. If an ID is defined it will be displayed

otherwise the slot number will be displayed.

Hovering the mouse over the tool selector will display a tool tip with information regarding the tool. Comment, Slot, ID, etc...

Besides changing tools with the T command, D and H commands are used to apply tool properties from the tool table.

Tool Numbers can be referenced by either Tool ID as a 4 digit (or higher) number or by Tool Slot as a 2 digit number.

A tool definition consists of a Tool Slot, Tool ID, the Length of the tool, the Diameter of the tool, XY offsets, a descriptive Comment, and a VRML Image File. All parameters are optional as long as either a Slot or ID is specified for each tool.

Note that the Tool Length can also be considered as a Z offset (Lathes often use this terminology).

Executing the **D#** command will select which Tool parameters are to be used for radius compensation (**G40,G41,G42**).

Executing the **H#** command will select which Tool parameters are to be used for XY compensation (**G43,G49**).

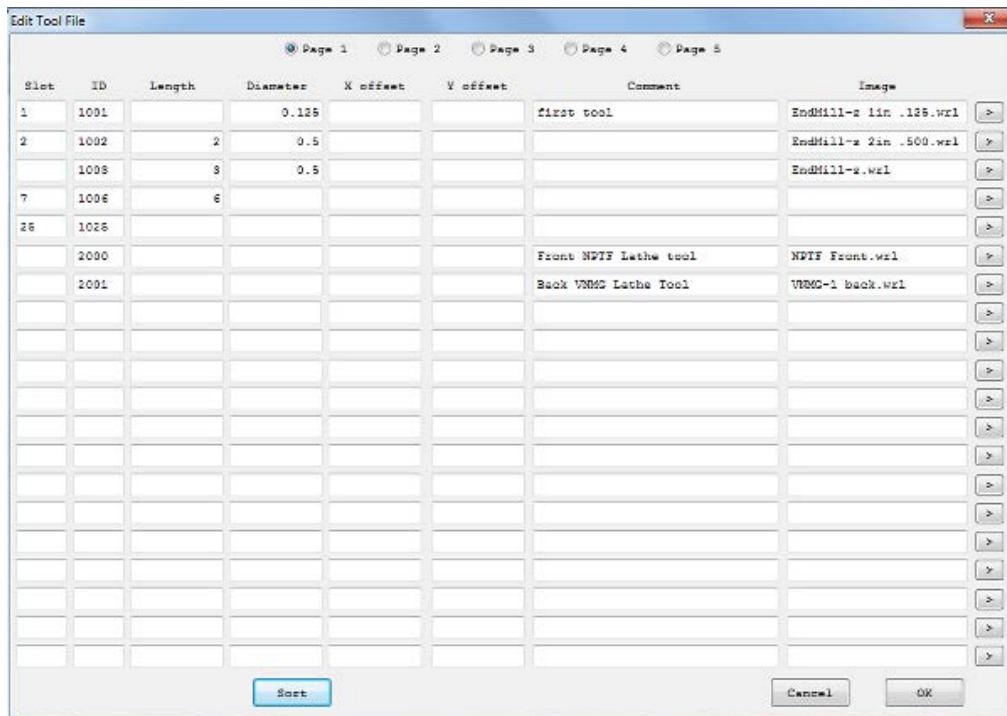

The Tool definitions are saved in a text file that is selected on the ToolSetup Screen. See below for an example Tool Table. There are 6 numeric and 2 alphanumeric strings. The strings, including empty strings, must be enclosed in quotes:

```

SLOT ID LENGTH DIAMETER XOFFSET YOFFSET COMMENT IMAGE
1 1001 6.000000 0.125000 0.000000 0.000000 "Long Endmill" "EndMill-z 1in .125.wrl"
2 1002 2.000000 0.500000 0.000000 0.000000 " " "EndMill-z 2in .500.wrl"
0 1003 3.000000 0.500000 0.000000 0.000000 " " "EndMill-z.wrl"
7 1006 6.000000 0.000000 0.000000 0.000000 " " "
25 1025 0.000000 0.000000 0.000000 0.000000 " " "
0 2000 0.000000 0.000000 0.000000 0.000000 "Front NPTF Lathe tool" "NPTF Front.wrl"
0 2001 0.000000 0.000000 0.000000 0.000000 "Back VNMG Lathe Tool" "VNMG-1 back.wrl"
26 0 1.000000 0.250000 0.000000 0.000000 " " "

```

The Tool Table may also be edited in a window using the **edit** button.

The Tool Edit Screen displays 20 tools per page over 5 pages for a total of 99 possible tools.

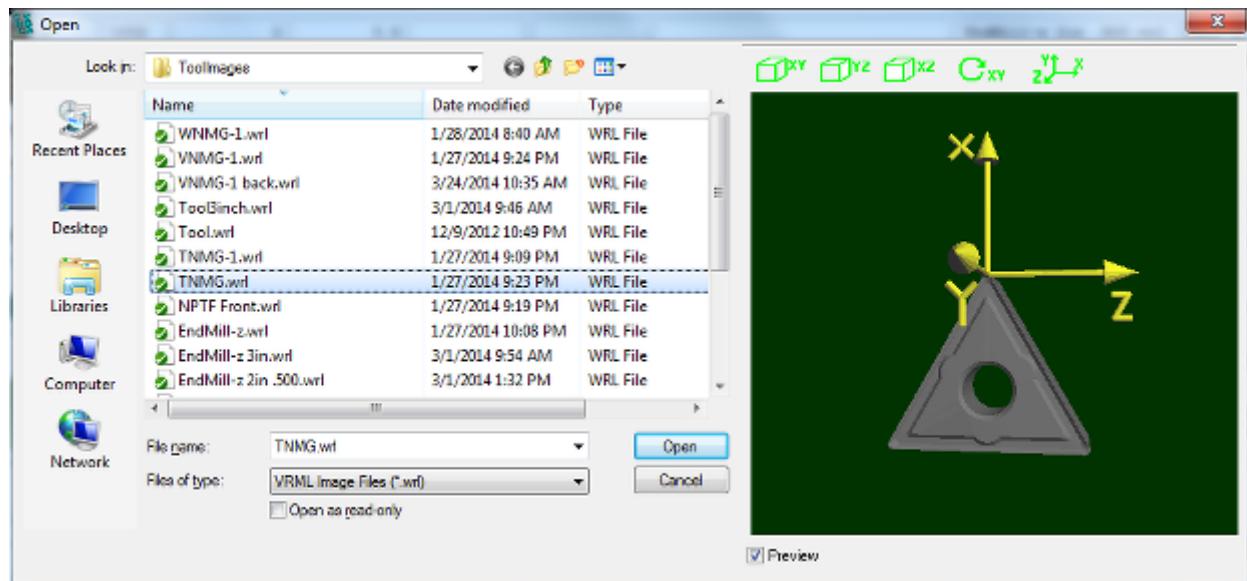

The normal idea is that all information regarding a tool is linked to a Tool ID. For a particular GCode Job specific Tools can be loaded into specific Tool Changer Slots and the corresponding slot numbers can be edited to reflect which tools are currently loaded.

A “Sort” button is available that will sort the Tool Table order first by Tool ID and the by Slot number.

The Tool Image file refers to a VRML 3D model of the Tool that will be used to display the tool when shown in the GViewer Screen. All image files are normally located into the <Install>\KMotion\Data\ToolImages Folder. VRML (Virtual Reality Modeling Language) files normally have a .wrl file type extension. If located in the standard

location no path is required to be specified. Pushing the Browse Button will bring up a File Selector Dialog with Preview that will display the available Tool Images as well as the Tool Image origin. Note that Mouse Click Right, Left, Both can be used to

manipulate the View in the same manner as in the GViewer Screen. For creating your own Tool Image files see information [here](#).

## File New / Open/ Save

This group of pushbuttons allow a G Code file to be loaded or saved to or from the edit window. The edit window allows the user to quickly switch between 7 loaded G Code files. Once a file is loaded into one of the edit windows, the name of that file will persist between sessions.

## Execute Controls

This group of pushbuttons allow the control of G Code execution. **Restart** will reset the instruction pointer to the first line of the file. **Cycle Start** will begin continuous execution from where the current instruction pointer is located on the left of the edit window. **Single Step** will execute one single line of G code where the current instruction pointer is currently pointing. Note that the instruction pointer may be moved to any line by right clicking on the line within the edit window and selecting Set Next Statement. The Keyboard F5 Key can be used to toggle Cycle Start/Halt.

**Halt** (available when GCode is running) will cause a feedhold to be initiated so that any coordinated tool motion will decelerate along the intended path. Once motion comes to a complete stop, the GCode Interpreter will abort and back up to the state of

the line of GCode that created the current Tool motion.

### Show Tool Setup / G Code Viewer Screens

This group of buttons brings additional screens into view. The [Tool Setup Screen](#) is used to configure the system's parameters. Machine Axis resolution/velocity/accelerations. M Code and User Button Actions Actions, Tool and Setup definition files, and Jog Button and Joystick rates. The [G Code Viewer Screen](#) allows real-time, 3D viewing of the machine tool paths either during actual machine operation or during simulation.

### G Code Edit Window

 A screenshot of a computer screen showing a text editor window titled "G Code Edit Window". The window displays a block of G-code. A right-click context menu is open over the text, listing options such as Undo, Redo, Cut, Copy, Paste, Select All, Find..., Replace..., Set Next Statement, Transform Sel, Toggle Block Delete '\', Show Line Numbers, and Make Read Only. The menu is displayed in a light gray box with a black border.
 

```

```

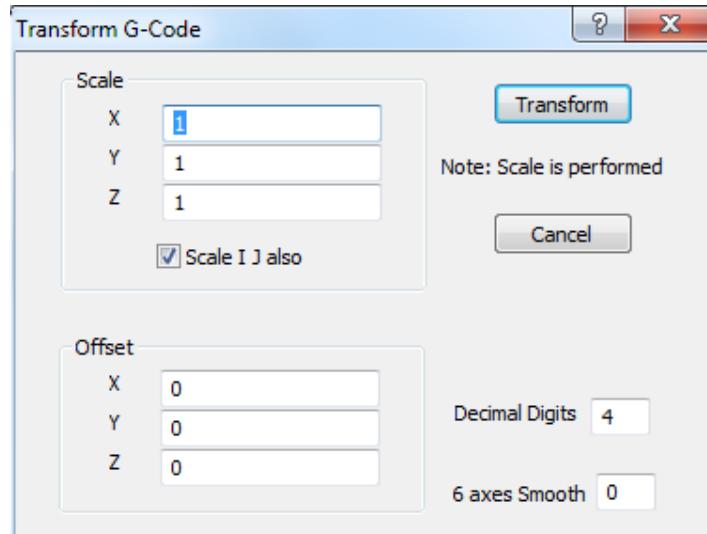

The Edit Window displays the loaded G-Code and allows editing. G-Code color syntax highlighting makes the code more readable. A right mouse click will bring up the context menu shown.

Unlimited **Undo/Redo** is supported by right mouse clicking or Ctrl-Z/Ctrl-Y hot keys.

**Find and Replace** is supported by right mouse clicking. Ctrl-F hot key for Find.

**Set Next Statement** can be used to move the current point of execution to the point where the mouse was clicked. A reverse search and analysis of the preceding lines will be performed to attempt to determine an appropriate starting position and conditions for the specified line. A Safe/Resume process and movement may be performed when execution is continued. Starting in the middle of a GCode sequence can be complex. It is up to the Operator to make certain that the state and current conditions are appropriate.

Note that **Transform Sel** will bring up a utility dialog (shown below) that allows the selected G-Code to be scaled or offset. The 6 axes *Smooth* option will measure an average between plotting points and allow for a smoother path. This feature is recursive, i.e. it can be repeated as many times as needed.

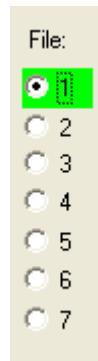

**Toggle Block Delete “\”:** When highlighting several lines of Gcode and then right-mouse-clicking, users can toggle between lines that will be executed and those that will not.

**Show/Hide Line numbers** can be selected to display GCode Line numbers in the Left Margin.

Users can set **Make Read Only** to avoid making any further changes. Select **Allow Read/Write** to revert to writeable (Note: will be undone automatically when program

restarts).

## **File Selector**

The file selector shows which of the 7 loaded G Code files is currently active for editing. The Main Window Title also displays the loaded filename for the selected file. The file number is highlighted in green when that file is currently executing G Code. Only one G Code file is allowed to execute at a particular time.

## **Simulate**

Enables Simulation Mode which allows viewing and verification of a G Code Program with or without any actual hardware connected. When Simulation mode is enabled no actual machine motion will be made. Executing or Single Stepping through a G Code program will change the Displayed Position and Plot the machine tool path on the [G Code Viewer Screen](#). In Simulation Mode the Numeric [Display](#) Color changes to white to indicate the display is not showing the actual machine tool position. While in Simulation mode the [Jog Buttons and Gamepad buttons](#) will also change the displayed position and tool position on the G Code Viewer Screen without causing any actual machine tool motion.

To perform a quick simulation for plotting or job extents verification the Run button may be used. Note that certain Jobs with manual operations, probing, etc. may not be possible to simulate.

## **Block Delete**

When checked, any line with a single '/' character at the beginning of the line will be deleted (skipped). When unchecked the line will be executed normally while ignoring the '/' character. The Initial state of Block Delete can be configured in the [Tool Setup File](#).

## Feed Hold

Feed Hold may be used to immediately decelerate all axes to a controlled stop. Any coordinated motion in progress will decelerate along the defined buffered path.

When stopped in feed hold, the button will be shown in a toggled state. To resume motion toggle the feed hold button off. Note that while stopped that the current GCode line may be advanced one or more lines past the current tool position because the Interpreter and Trajectory planner works ahead to allow motion to be buffered. [Halt](#) may also be selected to exit the feedhold state. Halt will cause the Interpreter to abort and back up to the GCode line that generated the current tool position.

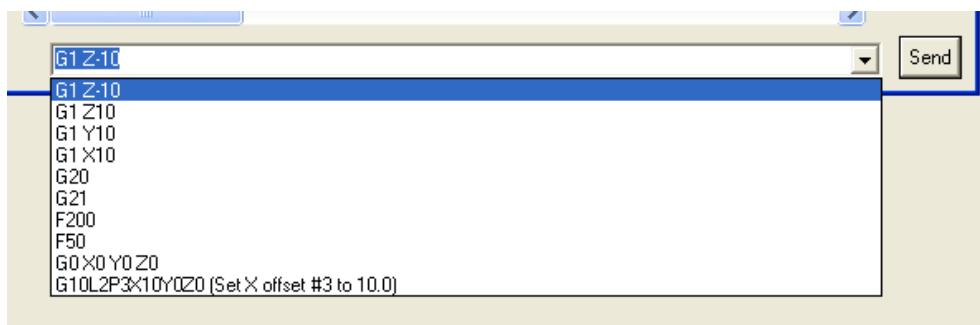

## Emergency Stop

Emergency Stop may be used to immediately stop all motion. Any commands in motion will be aborted and all axes will be disabled. After depressing Emergency Stop the system must be re-initialized and the G Code Interpreter state will be lost. Use Halt to stop in a controlled manner after the next line of GCode has been completed.

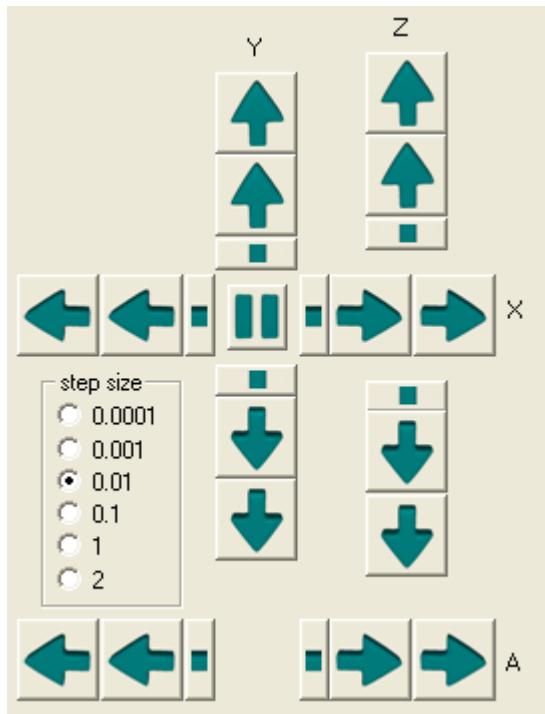

The ESC key may also be used to initiate an Emergency Stop whenever the KMotionCNC Screen has the focus.

## Manual Entry

The Manual Entry cell allows the user to quickly enter a single line of G Code and Send it to the interpreter for execution. The last 10 entered commands are saved in a drop down list for quick re-entry.

## Jog Buttons

the right joystick controls z and a. The same speed parameters in the Tool Setup Screen control both the Jog pushbuttons on the screen and the Gamepad.

The Jog buttons and Gamepad are also active in simulation mode

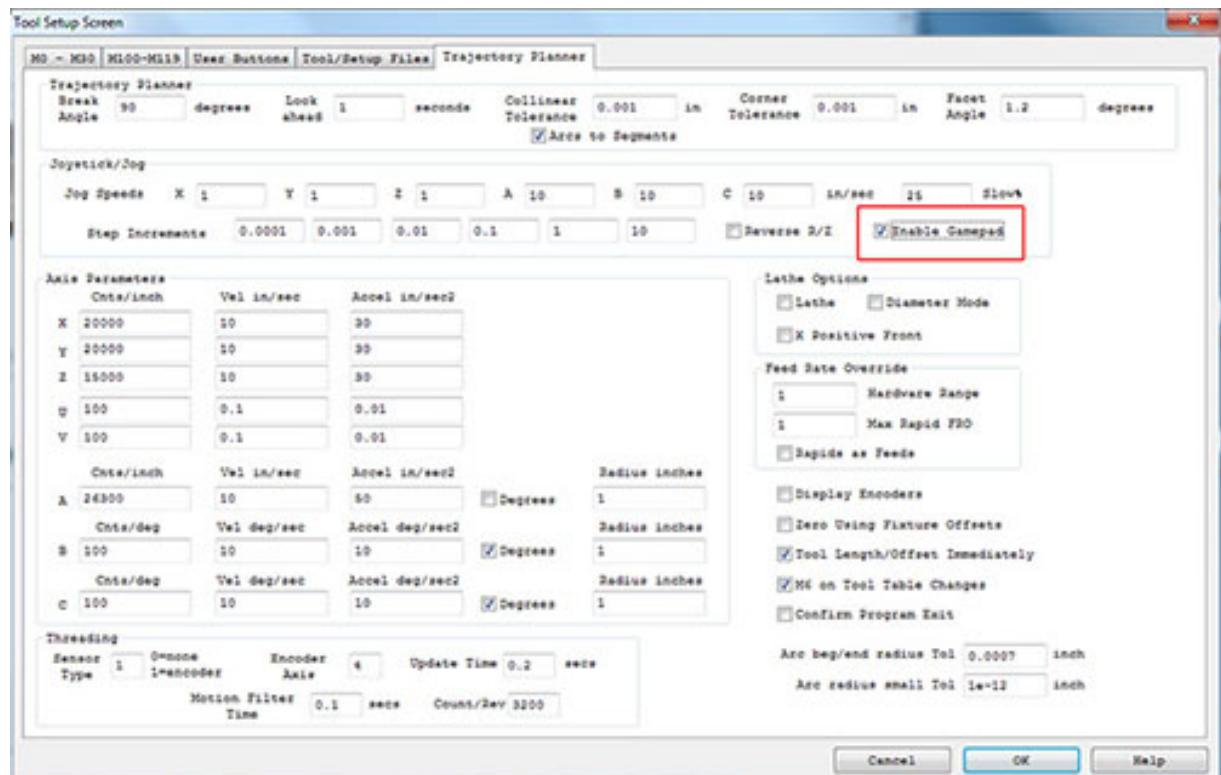

The Jog buttons may be used to move any of the axes. Pushing and holding any of the arrow buttons will cause continuous motion. There are 2 buttons in each direction for each axis. The second button moves at twice the rate as the first. The speeds for each axis may be specified in the [Tool Setup Screen](#).

There is also a Step button (square dot) for each axis and direction that will move an exact step size (as specified in the step size selection). The center button will stop a step in progress (useful for aborting large steps).

A USB Gamepad such as the one shown below or [Logitech's F310](#) may also be used to Jog the System. Simply connect the Gamepad and it should become immediately active. The left Joystick controls x and y and

The Jog buttons and Gamepad are also active in simulation mode. Note that you must check the box next to "Enable Gamepad" (by default unchecked) in the Tool Setup Screen/Trajectory Planner:

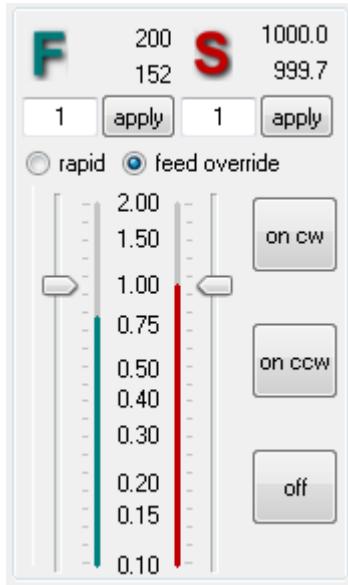

## Keyboard Jog

Toggling on Keyboard Jog allows keyboard keys that are normally used for Windows navigation to be used for Jog Functions. These include keys such as arrow, page up/down, +, - etc. Hovering the mouse cursor over a Button will display a tool tip that indicates a keyboard key that may be used instead of the mouse. Mouse clicking into an edit cell that requires the use of arrow keys will automatically de select Keyboard Jogging. The F2 key may be used to toggle Keyboard Jogging.

## Feed/Spindle Rate Override

Feed Rate Override (FRO) provides a means to adjust the feedrate while the machine is in operation without having to modify the G Code. The Feed Rate is specified within the G Code using the F command and the FRO is a multiplicative factor that is applied to that value. For example F100 would specify a Feed rate of 100 inches/minute (or 100 mm/minute if the interpreter is in metric mm mode), with a FRO of 1.5 the actual attempted feed rate would be 150 inches/minute (or 150 mm/minute in mm mode).

Note that this speed will only be used if all the axes involved will remain below the maximum allowed speeds set on the [Tool Setup Screen](#). Additionally, short vectors with sharp corners (greater than the specified break angle) that require stopping may be limited due to acceleration limits. KMotionCNC uses complex algorithms to ensure

that velocities and accelerations remain below user specified limits. If the FRO or (Specified Feed rate itself) doesn't seem to be having the expected result, check if the maximum velocities and accelerations are limiting.

The FRO may be changed either by using the slider or by typing a value and pressing the apply button.

Note that because motions are planned ahead and downloaded to the Motion Controller ahead of time, that the FRO will take a short amount of time to have an effect. The amount of time that the trajectory planner looks ahead is specified on the [Tool Setup Screen](#) and is normally set at from 1 to 3 seconds. The main limitation to making this value very short is the worst case response time of Microsoft Windows™ and the PC hardware being used.

Hardware Feed Rate Override (within KFLOP) can also be used for a more instant response. However Hardware FRO may result in distorted accelerations. Users can control how FRO is performed using the [Feed Rate Override Hardware Range Parameter](#).

Two numbers at the top of the screen show the last commanded F (Feedrate) setting and the actual instantaneous Feedrate. The actual Feedrate is also plotted as a bar graph as a ratio of actual feed rate to last programmed feed rate.

There is also an independently adjustable Rapid Rate Override, This can be displayed and adjusted by selecting the “rapid” selection. Rapid motions are performed in G Code for G0 type of motion. Rapid Rate Override always uses Hardware Override and has an

instantaneous effect.

Feed Rate can be unsynchronized as distance per time for G1,G2, G3 types of motion, or may be Spindle synchronized as distance per revolution for G32 types of Synchronized Threading Motions. When synchronized threading operation is in progress the Feed Rate Icon will be displayed as:  instead of simply as  for normal operations.

Similar controls and displays exist for Spindle Control and correspond to the last specified S value in the GCode.

Constant Surface Speed (CSS) is also supported which automatically varies the Spindle Speed as a function of cutting Radius in order to maintain a constant surface speed of the cutting tool across the material. G96/G97 Codes turn on and off this mode. When operating in CSS mode the Spindle Icon will be displayed as:  instead of simply as  for normal operations.

3 buttons allow the spindle to be turned on CW, on CCW, to the last specified S setting and SSO. If Spindle Speed feedback is available in the system, the current spindle speed (in RPM) and bar graph will display the ratio of actual Spindle Speed to last programmed Spindle Speed.

### **Custom Buttons**

KMotionCNC allows up to 5 Custom Buttons to be displayed and defined for special operations. Which of these buttons are visible, what they display as a title, and what action they perform are all definable on the [Tool Setup Screen](#).

The actions that the buttons perform are defined by the User in the same manner as the actions that M Codes perform. These may be simple actions such as setting an Output to turn something on or may be a complex operation that involves invoking a program. Normally one or more buttons will be used to initialize and configure the motion controller and/or home the machine.

### **Other GCode Commands**

**KMotion's** G Code interpreter was derived from the Open Source EMC G Code Interpreter. Click here for the [EMC User Manual](#) (Only the G Code portions of the manual, Chapters 10-14 pertain to **KMotion** G Code)

Specially coded comments embedded within a GCode program may be used to issue **KMotion** Console Script commands directly to **KMotion**.

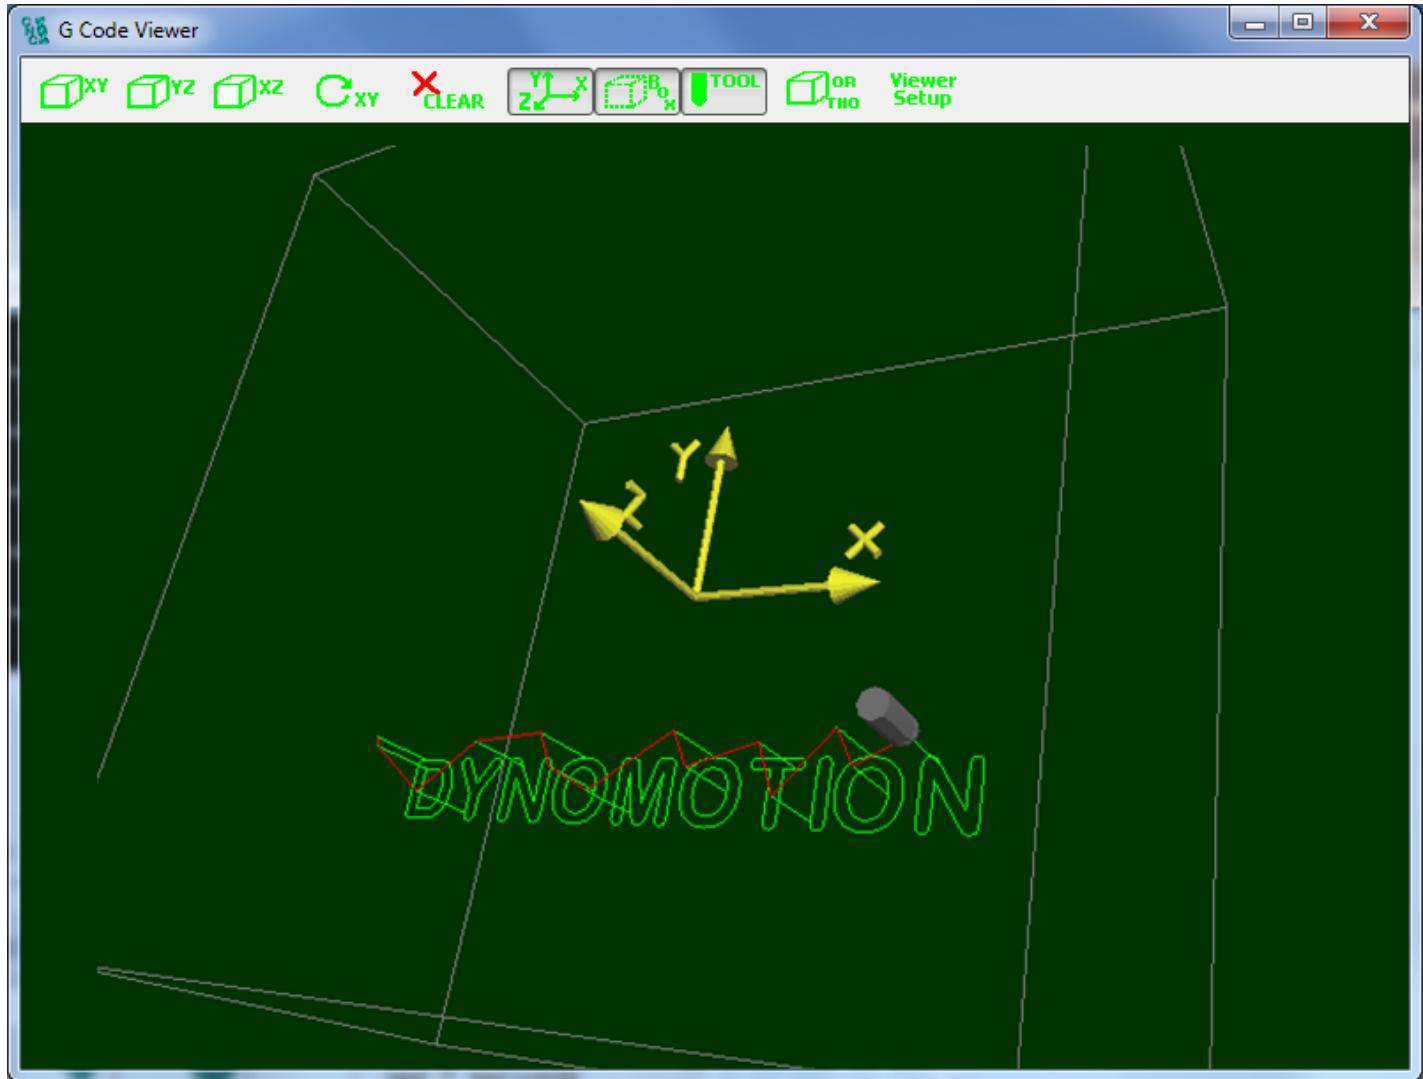

A comment in the form: (CMD,xxxxxx) will issue the command xxxxxx immediately to **KMotion** as soon as it is encountered by the Interpreter. Any **KMotion** command that does not generate a response may be used in this manner.

A comment in the form: (BUF,xxxxxx) will place the command xxxxxx into **KMotion's** coordinated motion buffer. Coordinated motion sequences are download to a motion buffer within **KMotion** before they are executed. This guarantees smooth uninterrupted motion. The BUF command form allows a command to be inserted within the buffer so they are executed at an exact time within the motion sequence. Only the following **KMotion** Script commands may be used in this manner.

SetBitBuf, ClearBitBuf, SetStateBitBuf.

Additionally, a comment in the form: (MSG,xxxxxx) will pause GCode Execution and display a pop-up message window displaying the message xxxxxx.

## G Code Viewer Screen

The G Code Viewer Screen displays the 3D motions of the machine tool as a GCode program is executing. To Display an entire G Code Program quickly without any physical motion of the machine tool, select Simulate on the main KMotionCNC Screen and execute the program. Linear and Circular Feed Motions (G1, G2, G3) are displayed as green paths. Rapid Motions (G0) are displayed as red lines. Note that rapid motions may not actually be performed as straight lines since during rapid motions each axis moves independently as quickly as possible.

Click and drag the **left** mouse Button to translate **up/down/left/right**.

Click and drag the **right** mouse Button to translate **closer or farther**.

Click and drag **both** mouse Buttons to **rotate**.

## Top/Side/Front Views

Use these buttons to view directly from the Top, Side, or Front respectively.

The camera is positioned at a distance away to view the entire box extents or current path extents whichever is greatest.

This is a latching toggle button. When latched down rotation is in the x y plane about the z axis. When unlatched, rotation is up/down/left/right.

Clears all path vectors. As a G Code Program executes motion paths are saved and displayed. Pushing this button clears all vectors from the internal buffer. All path vectors are also automatically cleared when the first line of a G Code program executes.

These are three latching toggle buttons which determine whether the Axis, Box, or Tool Shapes respectively are to be displayed. When latched down the item is displayed. When latched up the item is hidden. The size and shape of these items may be changed on the [G Viewer Setup Screen](#).

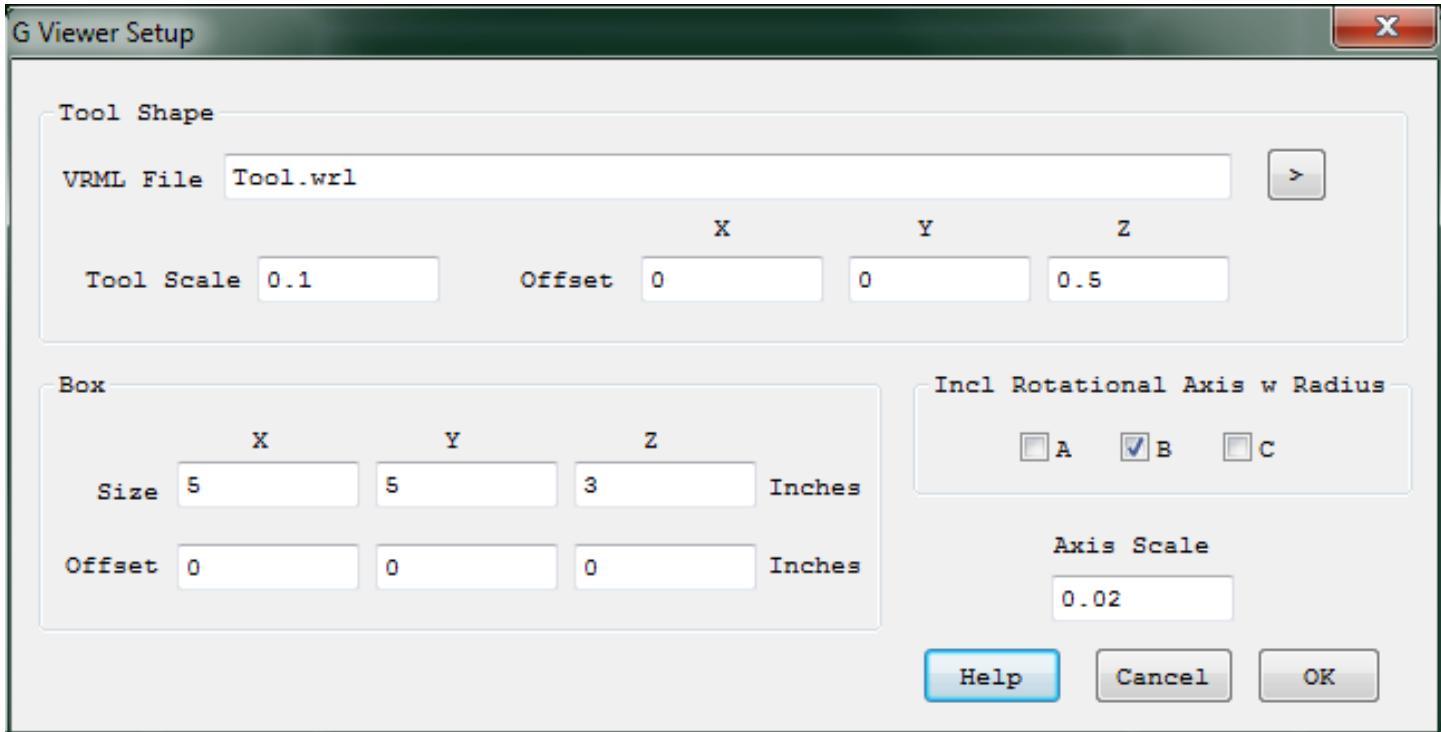

This button allows users to view the screen without 3D perspective. You can toggle between orthographic and perspective view. Note how in orthographic view the position of the cursor is visible in the title bar of your window:

This button brings up the [G Viewer Setup Screen](#) which allows some customization of the G Code Viewer Screen.

## G Viewer Setup Screen

The G Viewer Setup Screen sets the imaging parameters for the [G Code Viewer Screen](#).

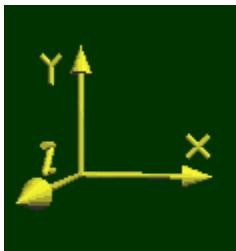

Besides the G code tools paths, the G Code Viewer Screen displays several objects, namely a Tool, a Box, and an Axis Symbol. The Tool Object and Axis Symbol are 3D VRML files that may be changed if desired. KMotionCNC comes with default files shown below.

### Tool Shape

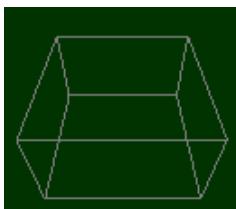

The default Tool Shape is located at: <Install Dir>\KMotion\Data\Tool.wrl, but maybe easily changed by entering or browsing to a new file. An excellent free program to create VRML files is available at <http://www.artofillusion.org>. The default Tool file is a 1 inch diameter sphere at the end of a 1 inch diameter cylinder which is 3 inches long. In the VRML file the origin (0,0,0) is at the center of the sphere. The Tool Scale and offsets allow the Tool Shape to be shifted and scaled as desired. As shown above an offset of (0,0,0.5) shifts the tool such that the origin is at the very tip of the tool. The scale of 0.15 then reduces the tool "size" from 1 inch to 0.15 inch. Specific Tool Shapes can be assigned to specific tools using the [Tool Table](#).

## Axis Scale

The Axis file name and location is hard coded as: <Install Dir>\KMotion\Data\Axis.wrl. The Axis shape is always drawn at the origin. Its size may be changed by changing the Axis Scale value. If a different Axis Shape is desired the Axis.wrl file must be overwritten with a new file. When Lathe Mode is selected a different Axis Style will be used based on the X Positive Front Setting as either <Install Dir>\KMotion\Data\AxisLathe.wrl or <Install Dir>\KMotion\Data\AxisLatheXFront.wrl.

## Box

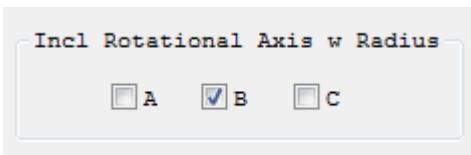

The Box serves two purposes. If enabled for display, it aids the 3D visualization and perspective of the tool paths. It is also expected to represent the working extents of the machine. When "zooming out" to one of the preset Top, Side, or Front Views, it is used to frame the view extents. Therefore the Box Size parameters should be set to the working extents of the machine. With an offset of 0,0,0 the origin will be located at the center of the Box. This is the preferred arrangement, however if required the Box may be displayed offset by entering Box Offset values other than zero.

## Include ABC angles

 Incl ABC angles

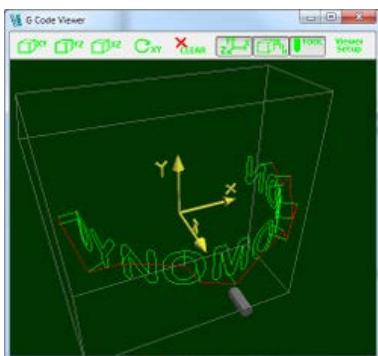

If checked, the A, B, and C angles of the tool are shown relative to the part. [See video.](#)

## Include Rotational Axes

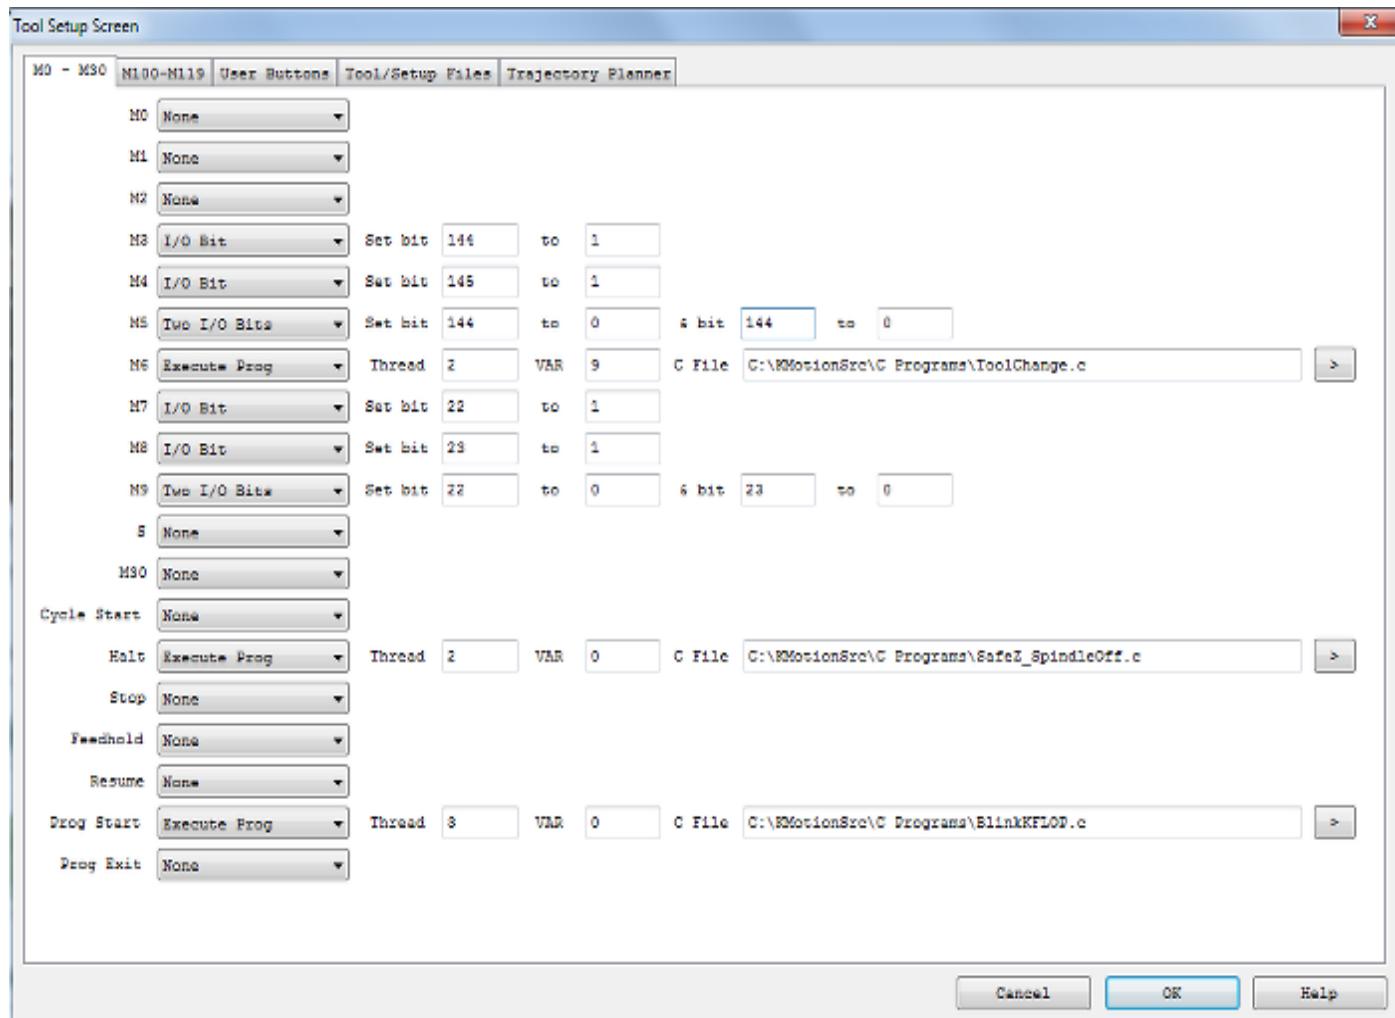

Includes the rotational effect of rotational axis if they represent a type of cylindrical dimension at a relatively fixed radius. The A axis rotates about the X Axis, the B axis rotates about the Y axis, and the C axis rotates about the Z axis. The example view below shows G Code plotted using B, Y , and Z Axes. The B motion is wrapped around the Y axis. The Z motion then moves away from the Y axis, and the Y motion is in the Y direction. [See video.](#)

motion is wrapped around the Y axis. The Z motion then moves away from the Y axis, and the Y motion is in the Y direction. [See video.](#)

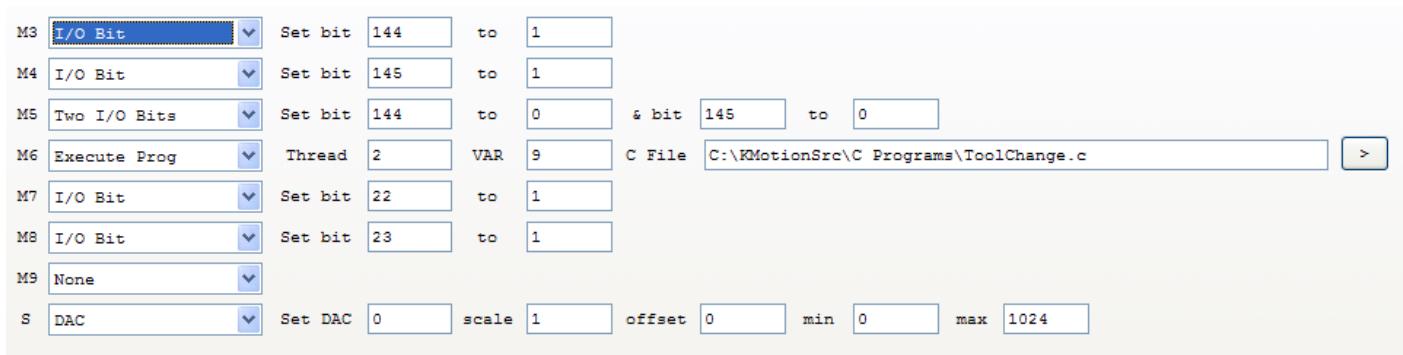

## Tool Setup Screen – M0 – M30

The Tool Setup Screen allows *KMotionCNC* to be configured for a particular machine tool. Each machine tool is likely to have different motion resolution, speeds, and acceleration limits. It is also likely to have different I/O requirements with regard to Spindle control and such. Additionally a machine may have different initialization and homing requirements. *KMotionCNC* has a flexible mechanism for defining what type of action is to be performed for various M Codes and Custom Buttons.

## G Code Actions – M0 – M30

The M Codes 0 through 9 have functionality commonly used by most machine tools. These can also be used as custom or general purpose M codes in the same manner as the M100-M119 M codes with the exception of M5 and M9 which are automatically executed on Program Stop or Rewind.

**M0** - Program Stop

**M1** - Optional Program Stop

**M2** - Program Stop, Rewind, Reset Interpreter Settings

**M3** - Spindle On CW

**M4** - Spindle On CCW

**M5** - Spindle Off - Note Automatically called on Program Stop/Rewind

**M6** - Tool Change (T variable is passed to the C program in the persist variable specified)

**M7** - Mist On

**M8** - Flood On

**M9** - Mist and Flood Off

**S** - Spindle Speed Setting. If C Program is specified Speed in RPM is passed to the specified KFLOP Var as a 32-bit floating point number

**M30** - Program Stop and Rewind

Additionally, Actions can be performed when certain KMotionCNC functions occur. These include:

**Cycle Start** - Action performed when the Cycle Start Button is pressed and before GCode begins execution

**Halt** - Action performed when the Halt Button is pressed after GCode stops execution. Commonly used to execute a C Program to move the Z axis to a safe height and turn off the Spindle. See the SafeZ\_SpindleOff.c as an example.

**Stop** - Action performed after Stop Button is pressed

**FeedHold** - Action performed after Stop Button is pressed

**Resume** - Action performed after FeedHold is released

**Program Start** - Action performed at KMotionCNC Program Startup

**Program Exit** - Action before KMotionCNC Program Exits

The Action that can be performed can be one of several things:

- None
- Set or Reset one I/O Bit
- Set or Reset two I/O Bits
- Set a DAC to a variable's value (S parameter)
- Wait (stall motion) until an Input to be in the specified state
- Execute a C Program in the KMotion Control Board
- Execute a C Program in the KMotion Control Board + wait for it to terminate
- Execute a C Program in the KMotion Control Board + wait for it to terminate + resync Interpreter positions
- Execute a Windows Program
- PC App Callback
- Screen Script File

To specify a particular action first select the Action Type. Each Action Type requires a different number and type of parameters. Next fill in the appropriate parameters. The one and two bit I/O commands are inserted directly into the coordinated motion control buffer. In this way they are exactly synchronized with any motion before or after the I/O commands. This is useful in systems where a fast shutter or other operation is required at precise times relative to the motion.

The five Action Types are described below:

For **one I/O** bit specify the I/O bit number and the state 0 or 1 to set it to.

For **two I/O** bits specify the I/O bit numbers and the state 0 or 1 to set each to. Often systems with two direction spindle control will require setting two outputs that control on/off and cw/ccw. This command is designed to handle those situations.

M5 **Two I/O Bits** ▾ Set bit 46 to 0 & bit 47 to 0

For a special command to pause motion until an external Input is activated select **Wait Bit** and specify the I/O bit number and the state 0 or 1 to wait for.

M6 **Wait Bit** ▾ Wait bit 46 till 0

For **DAC** specify the DAC (Digital to analog converter) channel number, how to scale and offset the associated variable, and the minimum and maximum allowed DAC settings. This command is primarily designed for use with the S (Spindle speed) G Code Command

S **DAC** ▾ Set DAC 0 scale 1 offset 0 min 0 max 1024

For **Execute Prog** specify the program Thread (1 through 7) where the program is to be downloaded and executed, a Persist Variable (0-199) that will be set before the program executes, and the name of the C Program to be Compiled, Downloaded, and Executed. This method is very powerful in that anything that may be programmed in C may be invoked. See the KMotion documentation and wiki ([http://www.dynomotion.com/wiki/index.php?title=KFLOP\\_C\\_Programs](http://www.dynomotion.com/wiki/index.php?title=KFLOP_C_Programs)) for information on writing C Programs for the KMotion Motion Control Board. There are a number of example C programs in the <Install Dir>\C Programs folder. The Example "\KStep\InitKStep3Axis.c" is an example which completely configures all necessary parameters in the KFLOP Board to drive 3 stepping motors using KSTEP's amplifiers.

Persist Variables are used for passing parameters and information to KFLOP before executing the C Program. The parameters are Action Specific. The 'S' Action will pass the Speed as a 32-bit Floating point value. The 'M6' Tool Change Action will pass the Tool Slot and Tool ID as 32-bit integer values in consecutive Persist Variables. MCodes can pass GCode PQR Parameters. See here (<http://dynomotion.com/Help/KMotionCNC/MCodesWithParams.htm>) for an example. If no parameter is associated with the Action, then the Action Table Index will be passed that can be used to inform the C Program which Action invoked it. Specifying a Var value as "-1" will not write anything into any variable.

Note that normally the \*.c Source Program File is specified, which simplifies making any changes as they will automatically be re-compiled and have effect. C Source programs are also independent of KFLOP Version as they are always Compiled to the current version before use. However it is possible to specify an \*.out binary file that has already been compiled for faster operation since it has already been compiled and only needs to be downloaded. When a file is compiled into binary

executable code it is compiled to run in a particular Thread space (memory specific) and also for a particular KFLOP Version. The compiler automatically marks the filename with (N).out. Where N is the Thread number that the code has been compiled to run in.

If the Filename is left blank, then it will be assumed that a program has been previously downloaded to the specified Thread and will just be re-executed. It is up to the designer to make sure a valid program has been downloaded and still exists in the specified Thread Space.

Additionally a program filename specified with a \*.ngc extension will be treated as GCode and the GCode Interpreter will be invoked to execute the GCode file. Note that the GCode Interpreter is not re-entrant (Interpreter can not call itself). This means that MCodes and other Actions invoked by the Interpreter can not Invoke GCode. This restriction also applies to C Programs that may in turn execute GCode. This essentially limits User Buttons and Special Commands (ie Program Start) to specifying GCode for execution. This functionality should be limited to simple GCode operations that should execute quickly.

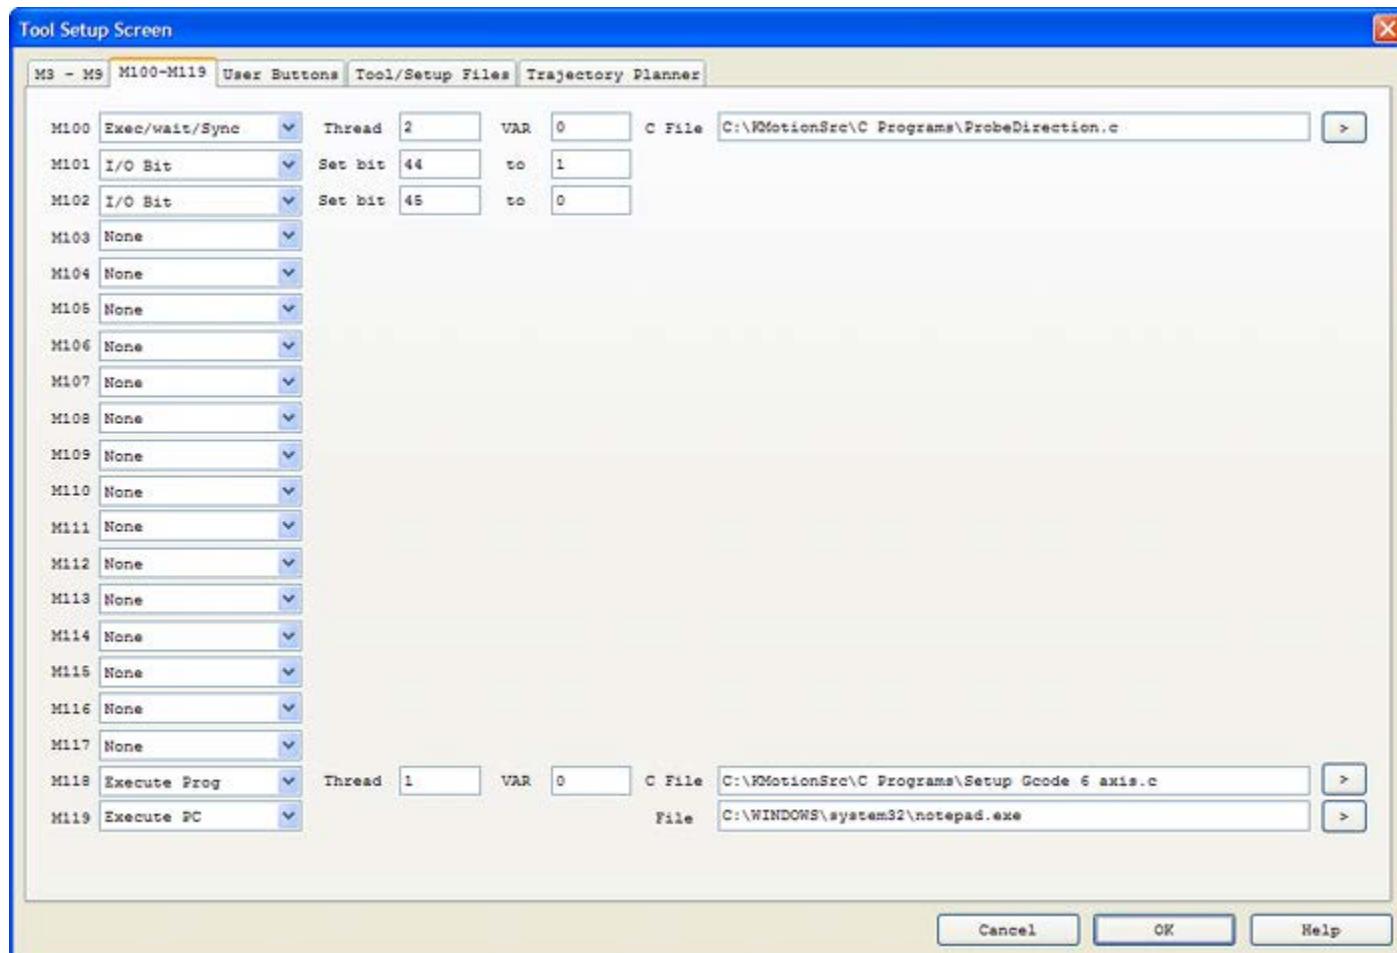

**PC App Callback** allows a user-compiled Callback Function to be called as an Action. However, this is a feature not commonly used unless you are modifying/recompiling KMotionCNC.

**Screen Script File** allows users to change/select different screen script files.

## Tool Setup Screen - M100 - M119

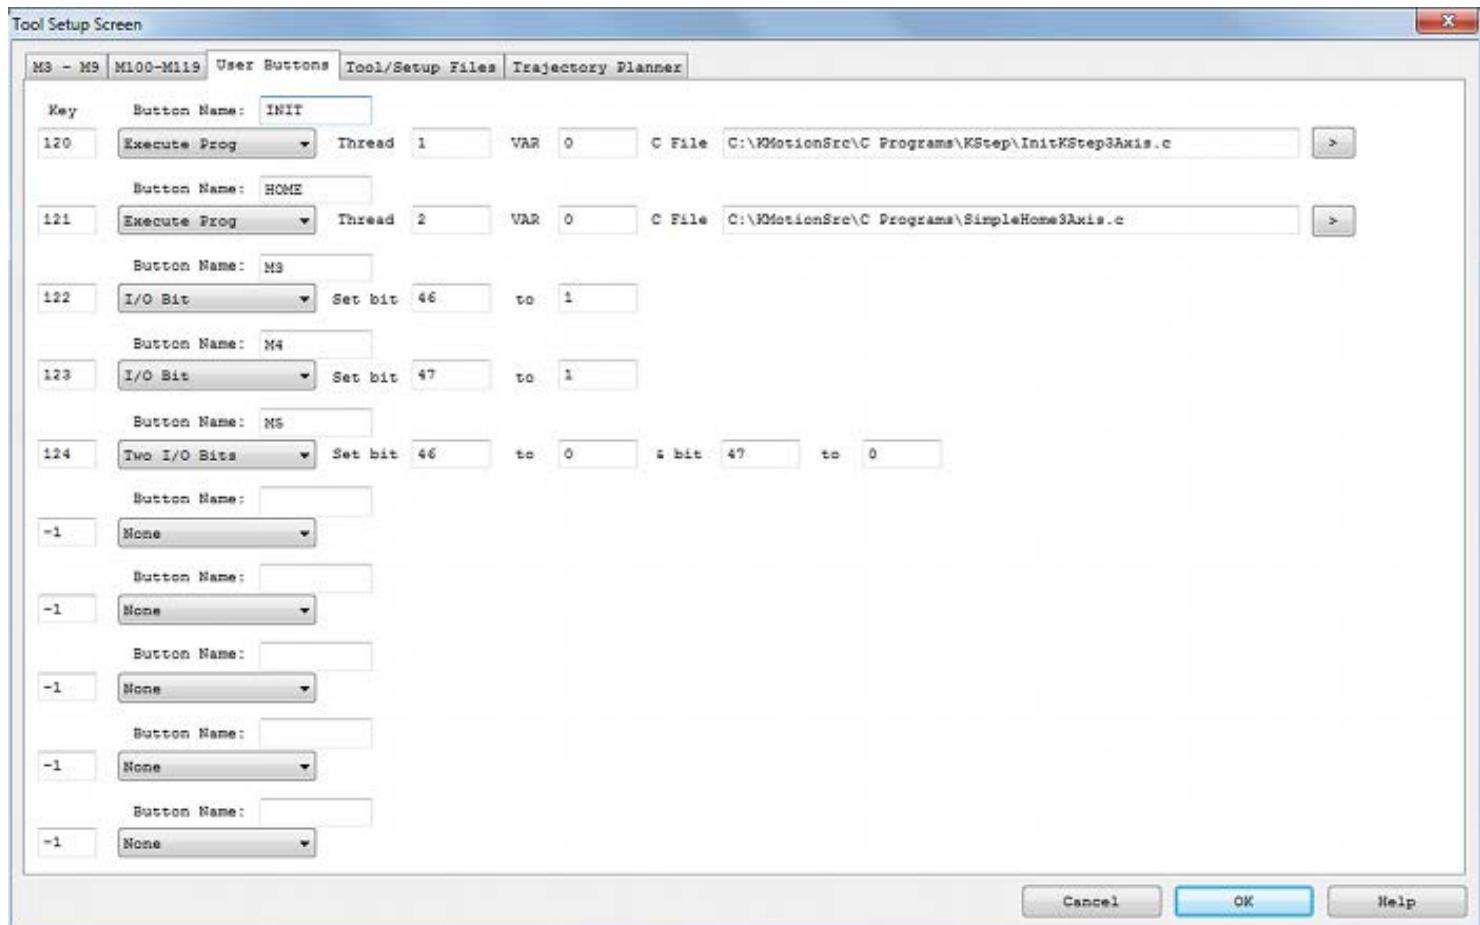

The Tool Setup Screen allows *KMotionCNC* to be configured for a particular machine tool. Each machine tool is likely to have different motion resolution, speeds, and acceleration limits. It is also likely to different I/O requirements with regard to Spindle control and such. Additionally a machine may have different initialization and homing requirements. *KMotionCNC* has a flexible mechanism for defining what type of action is to be performed for various M Codes and Custom Buttons.

### G Code Actions M100 - M119

This Tool Setup Screen Tab allows the user to define up to 20 custom general purpose M codes that can be used to change IO bits, or execute User C programs, or execute Windows Programs. The action to be performed is defined in the same manner as the [GCode Actions M3-M9](#) however parameters may also be passed from GCode to a KFLOP User C Program. [See also MCodes with Parameters.](#)

## Tool Setup Screen - User Buttons

The Tool Setup Screen allows *KMotionCNC* to be configured for a particular machine tool. Each machine tool is likely to have different motion resolution, speeds, and acceleration limits. It is also likely to have different I/O requirements with regard to Spindle control and such. Additionally a machine may have different initialization and homing requirements. *KMotionCNC* has a flexible mechanism for defining what type of action is to be performed for various M Codes and Custom Buttons.

## Custom Buttons

Key	Button Name:	INIT									
120	Execute Prog	▼	Thread	1	VAR	0	C File	C:\KMotionSrc\C Programs\KStep\InitKStep3Axis.c	>		
121	Button Name:	HOME									
121	Execute Prog	▼	Thread	2	VAR	0	C File	C:\KMotionSrc\C Programs\SimpleHome3Axis.c	>		
122	Button Name:	M3									
122	I/O Bit	▼	Set bit	46	to	1					

Custom Button Actions function in exactly the same manner as the [G Code Actions](#) described on the M3-M9 Tab with the only difference being that they are invoked by the User pushing a button rather than by a command encountered within a G Code Program. There is an additional Parameter above the Action Type which is the Title to be placed on the Custom Button. The example above shows buttons defined with titles "INIT", "HOME", "bit0", and "bit1". Up to 10 buttons may be defined. Common uses for the Buttons are to invoke programs that initialize and/or home the machine. Any Button with an empty title field will cause the button to be hidden on the main *KMotionCNC* screen. See [here](#) for how these defined buttons will appear in the main *KMotionCNC* Screen.

A Hot Key can also be assigned so that pushing that specific Key will trigger the Action as if the button was clicked with the mouse. The Screen must have focus for the Hot Key to work. See below for a list of numeric Virtual Key Codes:

## Key Codes

### Value Description

- 1 Left mouse button
- 2 Right mouse button
- 3 CANCEL key
- 4 Middle mouse button
- 8 BACKSPACE key
- 9 TAB key
- 12 CLEAR key
- 13 ENTER key
- 16 SHIFT key
- 17 CTRL key
- 18 MENU key
- 19 PAUSE key
- 20 CAPS LOCK key
- 27 ESC key
- 32 SPACEBAR key
- 33 PAGE UP key

---

34 PAGE DOWN key  
35 END key  
36 HOME key  
37 LEFT ARROW key  
38 UP ARROW key  
39 RIGHT ARROW key  
40 DOWN ARROW key  
41 SELECT key  
42 PRINT SCREEN key  
43 EXECUTE key  
44 SNAPSHOT key  
45 INS key  
46 DEL key  
47 HELP key  
144 NUM LOCK key

**KeyA Through KeyZ are the same as their ASCII equivalents: 'A' Through 'Z'**

**Value Description**

65 A key  
66 B key  
67 C key  
68 D key  
69 E key  
70 F key  
71 G key

## Tool Setup Screen - Files & Face

The Tool Setup Screen allows *KMotionCNC* to be configured for a particular machine tool. Each machine tool is likely to have different motion resolution, speeds, and acceleration limits. It is also likely to have different I/O requirements with regard to Spindle control and such. Additionally a machine may have different initialization and homing requirements. *KMotionCNC* has a flexible mechanism for defining what type of action is to be performed for various M Codes and Custom Buttons.

### Tool Table File

The Tool Table File specifies the disk text file which contains the table of tool definitions. In some cases the G Code Interpreter needs to know the length and diameter of the selected tool for tool path compensation. This file is used to define up to 99 tools. See also [Selecting Tools](#).

See below for an example Tool Table

```
POC FMS LEN DIAM COMMENT
1 1 0.0 0.0 first tool
```

```
2 2 0.0 0.0
3 3 1.0 0.5
4 4 2.0 1.0
32 32 0.0 0.0 last tool
```

## Setup File

The Setup File specifies the disk text file which contains the setup table for the G Code Interpreter. In some machine tools the Interpreter may require a special initialization state. Below is the default Setup file. Modifications to the setup file should not normally be required.

Attribute	Value	Other Possible Values
axis_offset_x	0.0	any real number
axis_offset_y	0.0	any real number
axis_offset_z	0.0	any real number
block_delete	ON	OFF
current_x	0.0	any real number
current_y	0.0	any real number
current_z	0.0	any real number
cutter_radius_comp	OFF	LEFT, RIGHT
cycle_r	0.0	any real number
cycle_z	0.0	any real number not less than cycle_r
distance_mode	ABSOLUTE	INCREMENTAL
feed_mode	PER_MINUTE	INVERSE_TIME
feed_rate	5.0	any positive real number
flood	OFF	ON
length_units	MILLIMETERS	INCHES
mist	OFF	ON
motion_mode	80	0,1,2,3,81,82,83,84,85,86,97,88,89
plane XY YZ, ZX		
slot_for_length_offset	1	any unsigned integer less than 69
slot_for_radius_comp	1	any unsigned integer less than 69
slot_in_use	1	any unsigned integer less than 69
slot_selected	1	any unsigned integer less than 69
speed_feed_mode	INDEPENDENT	SYNCHED
spindle_speed	1000.0	any non-negative real number
spindle_turning	STOPPED	CLOCKWISE, CCLOCKWISE
tool_length_offset	0.0	any non-negative real number
traverse_rate	199.0	any positive real number

## Geo File

Geometric correction file. Allows correcting errors in the the x,y,z positions. The calibration procedure involves moving the tool tip to an xy array of positions. For example, a precision grid might be printed on a glass or Mylar plate. By Jogging the tool tip to each row and column grid point and recording the machine's x,y,z position, a table of machine coordinates that correspond to perfect coordinates may be obtained. The "measure" button on the main KMotionCNC Screen may be used to log these positions. If such a table is specified here, the system will correct machine coordinates by bilinear xy interpolation of this table. Z is corrected for flatness at the plane of z=0 only.

The table format is shown below.

The first line specifies the number of rows and columns in the table.

The second line specifies the delta x and delta y between gridpoints.

The third line defines any Table x,y offset. With an offset of 0,0 grid point row=0,col=0 will correspond to x=0, y=0. Specifying an offset will shift the table so that row=0, col=0 will correspond to the offset position. For example if the machine coordinates are such that the origin is in the middle of the range of travel, then a negative offset would be specified.

The remaining lines are row, column, x, y, z table entries.

For more information see [Geo Correction Table](#).

## Vars File

The Vars File is used to save all the GCode Variables which contain [Fixture Offsets](#) as well as other values. When Variables are saved to disk the file must already exist which lists which variables are to be saved. The file is read and all the variables present in the file will be replaced with their current values. Variables 5221-5226 contain the XYZABC coordinates of the first fixture offset. Skip 20 for each successive fixture.

## Main Dialog Face

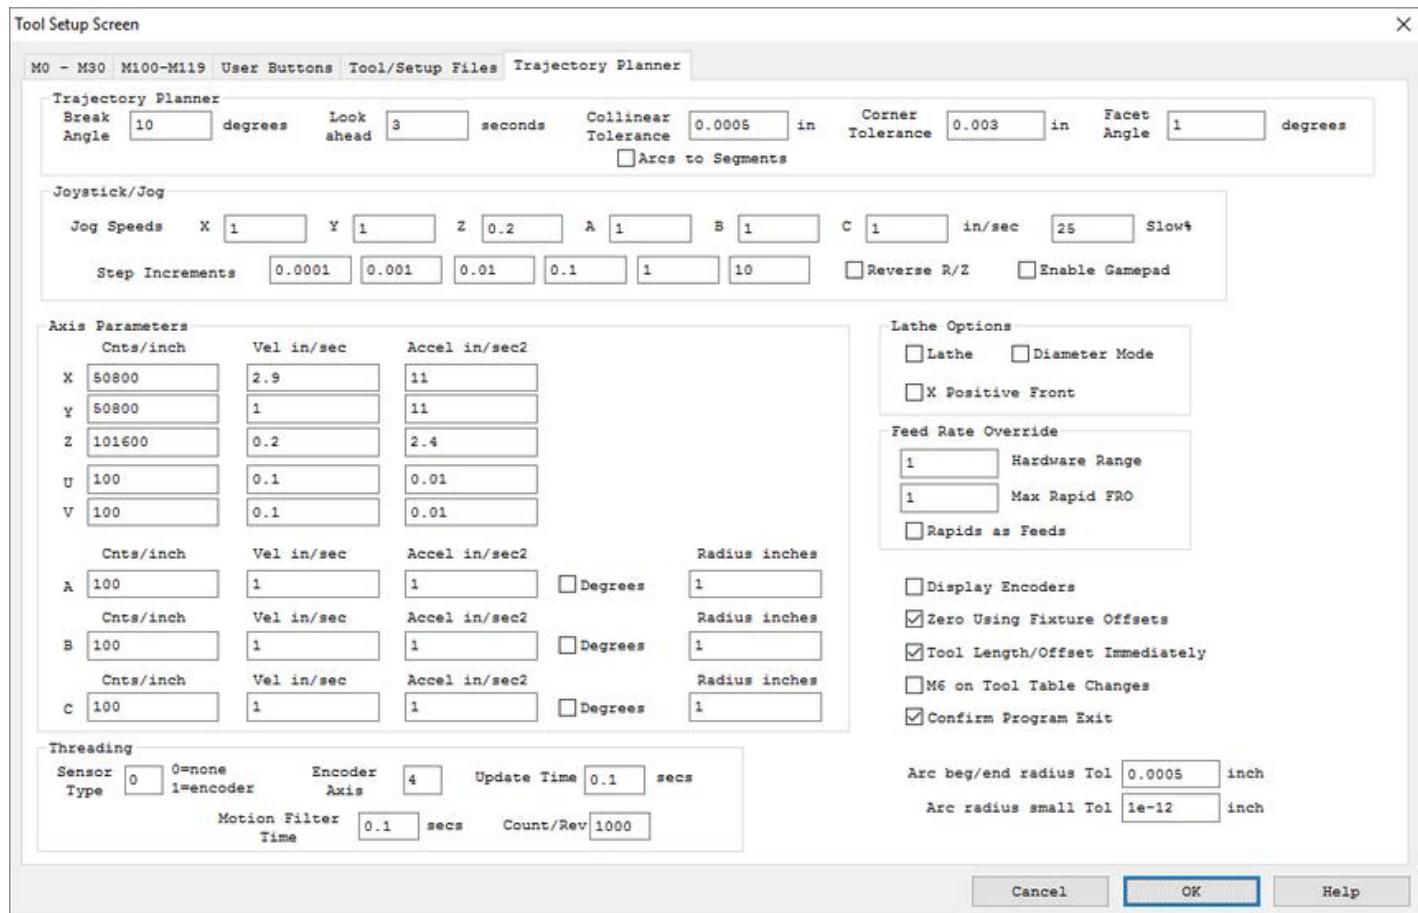

The Main Dialog Face selection selects the look of the main operation screen for KMotionCNC. Currently there are several available selections. The main difference is the number of axes, DROs and jog buttons. It is also possible to alter the dialogs by using a Windows™ Resource Editor in Microsoft Visual Studio.

By selecting "Custom", users can load cusom screen script files which can be created and modified using the [KMotionCNC Screen Editor](#).

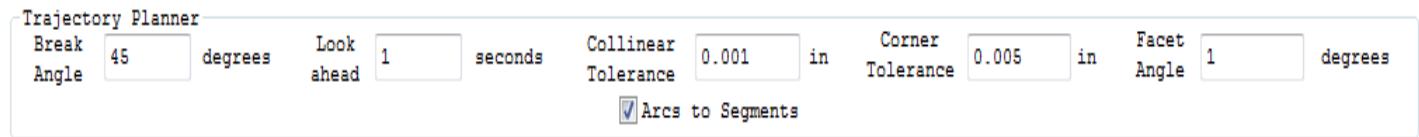

## Tool Setup Screen - Trajectory Planner

The Tool Setup Screen allows *KMotionCNC* to be configured for a particular machine tool. Each machine tool is likely to have different motion resolution, speeds, and acceleration limits. It is also likely to have different I/O requirements with regard to Spindle control and such. Additionally a machine may have different initialization and homing requirements. *KMotionCNC* has a flexible mechanism for defining what type of action is to be performed for various M Codes and Custom Buttons.

## Trajectory Planner

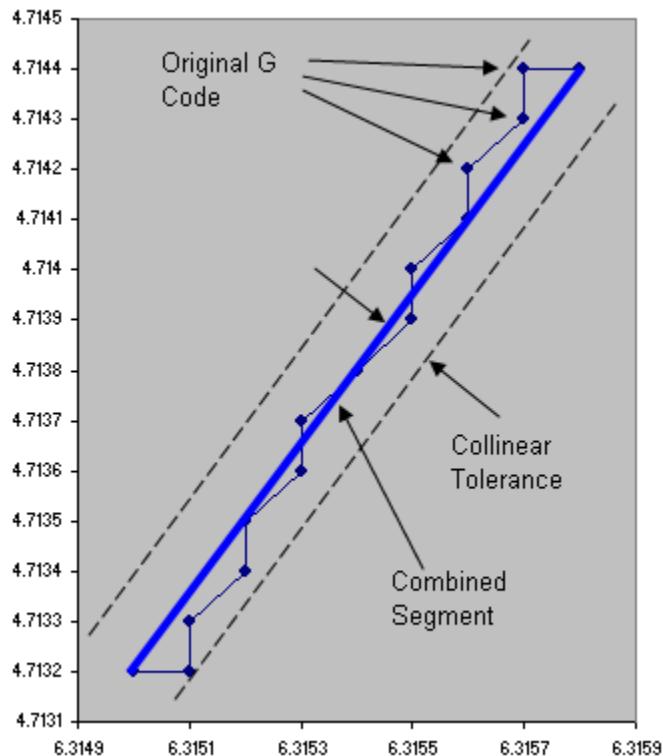

KMotionCNC contains a powerful Trajectory Planner. The Trajectory Planner utilizes a "break angle" concept to decide when a stop must be made. Vectors that are in the same direction within the "break angle" are traversed without stopping. When a "sharp" angle is detected a complete stop will be made before beginning on the next vector. The Break Angle Parameter allows the user to specify the angle in degrees that will be considered a "sharp" angle. KMotionCNC considers the change in direction in 3 dimensions (x,y,z ignoring a). The Trajectory Planner is capable of optimizing the acceleration and deceleration through many short (or long) vectors all of which may have different acceleration and velocity limitations.

The Trajectory Planner also has a "lookahead" parameter. With KMotionCNC the G Code Program itself, the G Code Interpreter, and the Trajectory Planner all reside within the PC running Microsoft Windows™. Since the Microsoft Windows™ is *not* a real-time OS, a certain amount of motion must be buffered in the motion controller to handle the cases where the PC program doesn't have a chance to execute for a while. These time periods are typically very short (a few milliseconds), but in some extreme cases may occasionally be as long as one or several seconds. The worst case is often a factor of the hardware (disk network adapters, etc) and associated drivers that are loaded into the system. The lookahead parameter is used to determine how much motion, in terms of time, should be downloaded to the motion controller *before* actual motion is initiated. Furthermore, after motion has begun, the lookahead parameter is used to pause the trajectory planner to avoid having the Trajectory Planner get too far ahead of the actual motion. The disadvantage of having the Trajectory Planner get too far ahead is that if the User decides to override the feed rate, since the motion has already been planned and downloaded, the rate will not be changed quickly. A value of 3 seconds is very conservative on most systems. If more responsive feed rate override is desirable, an experiment with a smaller value might be made.

"Collinear Tolerance" allows GCode blocks that are nearly linear, to be combined into a single linear segment to allow faster and smoother motion. Often GCode programs generated by 3D CAD systems contain very small vectors that appear jagged or noisy due to numerical round off errors . See below for an example of a small GCode fragment from an intended circle. The 0.3 inch diameter circle was divided into 10,000 sides each only 0.0001 inches in length. Intuitively one would think this would result in an extremely smooth contour. Ironically, rounding off to 4 decimal digits introduces "noise" that results in sharp angles and each axis being required to repeatedly stop and start. Even with quite high acceleration, stopping and starting over short distances results in extremely low average speed and most likely a rough surface. A combined segment shown below in blue will result in a faster and smoother motion.

Segments are combined as long as all intermediate waypoints do not deviate from the combined segment by more than the allowed collinear tolerance. Setting the collinear tolerance to zero will disallow any segments from being combined.

```
N70 G90 G54 G0 X6.315 Y4.7132 Z1.
N100 G1 X6.3151 F60.
N110 Y4.7133
N120 X6.3152 Y4.7134
N130 Y4.7135
N140 X6.3153 Y4.7136
N150 Y4.7137
N160 X6.3154 Y4.7138
N170 X6.3155 Y4.7139
N180 Y4.714
N190 X6.3156 Y4.7141
N200 Y4.7142
N210 X6.3157 Y4.7143
N220 Y4.7144
N230 X6.3158
```

The "Arcs To Segments" option allows circular arcs that were specified in the original GCode to be replaced by a number of linear segments. Each arc will be recursively subdivided until any cord error deviation from the original path is less than the Collinear Tolerance parameter. Sub dividing the arc (actually a helix) into line segments allows the path motion to be more fully optimized by the Trajectory Planner. This is because as the motion progresses through the arc the direction changes. As the direction changes the different axes become involved and also work together in different ways (diagonal directions make use of more than one axis). This means constraints (max velocity and acceleration) vary throughout the arc. With individual line segments the Trajectory planner is able to use optimal acceleration and velocity throughout the arc. When Arcs To

If Segments is not selected the entire arc may be treated as a single entity and will use the most limited velocity and acceleration constraints throughout the arc for the entire arc. If the feed rate is slow and curvature based accelerations are small relative to the axis limits then there will be little performance increase in using segments.

When the "Arcs To Segments" Option is selected the Collinear Tolerance must be larger than zero. Care should be used in selecting a Collinear Tolerance so that an excessive number of segments is not generated. The number of segments increases as the square root of the inverse of the Collinear Tolerance (cutting the tolerance in half increase the number of segments by 40%).

For a description of the *Corner Rounding* feature and Corner Tolerance and Facet Angle see [here](#).

## Jog Speeds

Jog Speeds	X 1	Y 1	Z 1	A 10	B 10	C 10	in/sec	25	Slow*
------------	-----	-----	-----	------	------	------	--------	----	-------

Defines the Jog Speeds for both the Jog Buttons and any attached Gamepad controller. These speeds are the maximum Jog speeds which are indicated by the outer jog arrow buttons (Jog Fast) or the GamePad joystick fully depressed. The user can define a slower speed as a percentage of the fast speed. See Also [Jog Buttons](#).

## Step Increments

Step Increments	0.0001	0.001	0.01	0.1	1	10	Reverse R/Z	<input checked="" type="checkbox"/> Enable Gamepad
-----------------	--------	-------	------	-----	---	----	-------------	--

Defines the step size distances for the Step Buttons that are displayed on the main *KMotionCNC* Screen. Setting a step size to zero will hide the size selection. The Reverse R/Z may be selected if the GamePad Z motion is reversed on a particular GamePad device. The *Enable Gamepad* checkbox allows you to enable or disable a gamepad. Some systems falsely indicate that they have a gamepad installed, which may cause errors. In these cases, uncheck the *Enable Gamepad* checkbox. See Also [Jog Buttons](#).

## Lathe Options

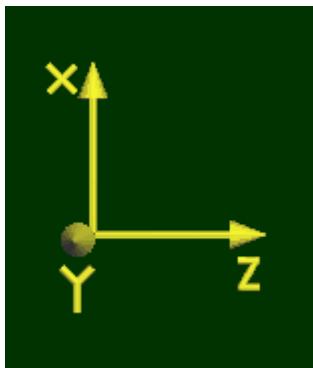

Lathe Options	
<input checked="" type="checkbox"/> Lathe	<input type="checkbox"/> Diameter Mode
<input checked="" type="checkbox"/> X Positive Front	

Defines options relating to Lathe systems.

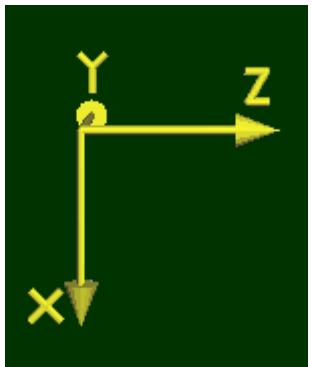

Selecting the Lathe option orients the Jog Buttons and default GViewer orientations to have +Z horizontal to the right and with X vertical as most Lathe systems are configured. The "X Positive Front" rotates the axes system (and X Jog Keys) so that the tool moves toward the front of the

system as X increases. This is more suitable for cutting tools mounted on the front side of the spindle. Otherwise the tool moves toward the back as X increases. This is more suitable for read mounted tools.

#### X Positive Rear

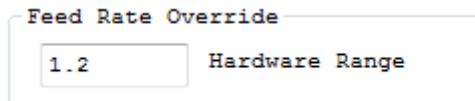

#### X Positive Front

When Diameter Mode is selected the Gcode X Units, X Offset Units, and X DRO Units are all in terms of diameter. In this mode actual tool cutter motion is 1/2 the specified value so the total diameter of the cut part is the specified value. When Diameter Mode is not selected, Radius mode will be used, the tool cutter motion will be the specified value, and the cut part will have a radius of the specified value in the GCode.

## Feed Rate Override

The Hardware Range value allows control over what part of the Feed Rate Override (FRO) Range is handled by Hardware, and what part is handled by Software (Trajectory Planner).

Hardware FRO has the advantage of having instant response, however it has a disadvantage of having accelerations distorted by time warping. Accelerations will be distorted by the square of the FRO setting. For example a FRO of 2.0 will result in accelerations 4X higher than planned. Hardware FRO can be thought of like playing a movie back in fast or slow motion. Another analogy might be a car that plans a trajectory accelerating from 0 to 60MPH in 10 seconds. Played at double time (FRO=2.0) would result in acceleration from 0 to 120MPH in 5 seconds! Similarly feed rates through tight curves will be proportionally increased by the FRO possibly resulting in excessive acceleration. Velocities are also increased proportionally by the Hardware FRO. This is obviously the normal intention, however speeds at or near the maximum possible for the system may now exceed the capabilities of the system. This also applies for Rapid (G0) motions. Any Hardware FRO value higher than 1.0 must have maximum system settings set in a manner that accelerations and velocities have sufficient margins to allow this increased acceleration and velocity.

Hardware FRO values less than 1.0 will be distorted in the opposite manner. Accelerations will be unnecessarily slow. In the previous car analogy played at slow motion (FRO=0.5) the car would accelerate from 0 to 30MPH in 20 seconds. Motions through tight curves will be proportionally slowed down regardless if a higher speed might be possible and closer to the desired feed rate. Hardware FRO values less than 1.0 will never cause a maximum acceleration or velocity limit to be exceeded.

Software FRO always provides the optimal motion without ever exceeding any system constraint. Maximum Accelerations and Velocities on all axes will always be honored. Accelerations to feed rate will always be optimized. Speeds through curves will always be optimal. However such optimized Trajectory Planning is complex and requires look ahead and results in some delayed response to changes. Reducing [lookahead](#) can minimize this delay.

The FRO Hardware Range Parameter sets the boundary FRO value where values below the setting will be handled by Hardware, and values above the setting will be handled by Software. Here are some examples:

Hardware Range = 0.0 will cause *all* FRO values to be handled by Software.

Hardware Range = 100.0 (a huge value) will result in *all* FRO values being handled by Hardware.

Hardware Range = 1.0 will cause all values less than 1.0 to be handled by Hardware and values greater than 1.0 to be handled in Software. This is the largest value that will never cause the set values of Max Acceleration or Max Velocity set in the Trajectory Planner to be exceeded.

Hardware range = 1.2 will cause all values less than 1.2 to be handled by Hardware and values greater than 1.2 to be handled in Software. This setting is useful if it is required to have minor increases (+20%) and all decreases have an instant effect. However this requires that the set values of Max Acceleration or Max Velocity set in the Trajectory Planner be set by a factor of  $1/1.2^2 = 0.69$  of the system capabilities in order to provide margin to allow for the Hardware FRO.

Hardware Range = 0.5 will cause all values less than 0.5 to be handled by Hardware, and values greater than 0.5 to be handled in Software. In most cases this will result in a similar result as Hardware Range = 0.0 (with all changes handled by Software). However in cases for example where the FRO is suddenly reduced from 1.0 to 0.25 the system will first reduce the FRO to 0.5 in Software, and then the remainder, another factor of 0.5 in Hardware. The Software effect will be delayed but the hardware effect will be instant. This provides most all of the benefits of Software FRO in the normal ranges of (ie 0.9 - 1.1) while also allowing a means of instantly slowing down.

## **Max Rapid FRO**

 **1.2**      **Max Rapid FRO**

Limits the Rapid FRO to the specified value. Rapid FRO is always performed in hardware so values Rapid FRO values greater than 1.0 will exceed the specified Velocity, Acceleration, and Jerk specified in KFLOP. Use this limit to avoid FRO values that would cause Velocities, Accelerations, or Jerks that the system would be incapable of performing. This value is commonly set to 1.0 if the parameters specified in KFLOP are set at the maximum possible. To allow FRO values greater than 1.0 the system must have sufficient margin to be able to exceed the specified parameters. Values less than 1.0 are not commonly specified.

## **Rapids as Feeds**

 **Rapids as Feeds**

Selects whether Rapids are performed as 3rd-order (Jerk limited) motions or 2nd order Feed Motions. Most systems will not select this option so that Rapids are performed as faster/smoothier 3rd-order Jerk-Limited motions. However KFLOP performs 3rd order Rapids as a single linear interpolated multi-axis motion at the actuator level. This is fine for normal Cartesian xyz linear systems however may cause problems for highly non-linear kinematic systems as a straight line in actuator space is not likely to be a straight line in real CAD space. For example a Delta Platform is an example of a non-linear system. This may result in a rapid motion path from one point to another to be along a somewhat unpredictable curved path. In some cases this may result in an undesirable crash. [Geometric Correction](#) is also a form of nonlinearity. However Geometric correction is usually not sufficiently non-linear to cause problems unless long rapids are performed passing very close to part surfaces or features. If nonlinearity is an issue for your system, select this option and Rapids will always be performed along a straight line as they will be subdivided into

small segments where proper actuator positions are calculated to keep the motion along a straight line. Regardless of whether this option is selected or not the Velocity and Acceleration will be set by the KFLOP Axis Parameters not by the current GCode Feed Rate or Trajectory Planner Settings.

## ***Display Encoders***

Displays in the DROs the Measured Encoder Position for axes that are configured with an Input Mode other than None. When Un-checked all DROs display the commanded position.

## ***Zero Using Fixture Offsets***

Zero/Set Buttons near DROs allow the User to Set the DRO to Zero or a Specified Value. This is accomplished by adjusting GCode Offsets. When this option is selected then the currently selected Fixture Offset will be adjusted. When unchecked the Global G92/G52 Offset will be adjusted.

## ***Tool Length/Offset Immediately***

This option causes the KMotionCNC Drop Down Tool Selector to immediately select and apply the Tool Length (and offsets) Compensation without having to select and turn on the compensation in GCode with "HxxxxG43".

## ***M6 on Tool Table Changes***

This option causes the automatic execution of an TxxxM6 operation after the Tool Table has been edited to re-select the specified Tool so the selected Tool ID, slot, offsets, image all reflect the current state of the Tool Table.

## Confirm Program Exit

Confirm Program Exit

By default checked, this option prompts a confirmation that the user wants to exit KMotionCNC.

## Arc beg/end radius Tol

Arc beg/end radius Tol  inch

The GCode indirectly specifies the Start of the Arc (previous position), the End of the Arc (Specified Position), and the Arc Center Point (Previous Position + IJK offset). The distance between the Start to the Center and the End to the Center should be the same. Specifies the allowed Tolerance the GCode Interpreter will allow between the beginning and ending radius of an arc. This should be a very small number within the rounding tolerance of the numbers.

## Arc radius small Tol

Arc radius small Tol  inch

Tolerance parameter for allowing Arc Radius being smaller than half the distance from the start of Arc to End of Arc when specifying Arcs using R mode.

## Axis Motion Parameters

Axis Parameters					
	Cnts/inch	Vel in/sec	Accel in/sec <sup>2</sup>		
X	<input type="text" value="10000"/>	<input type="text" value="10"/>	<input type="text" value="40"/>		
Y	<input type="text" value="10000"/>	<input type="text" value="10"/>	<input type="text" value="40"/>		
Z	<input type="text" value="10000"/>	<input type="text" value="10"/>	<input type="text" value="40"/>		
	Cnts/deg	Vel deg/sec	Accel deg/sec <sup>2</sup>		Radius inches
A	<input type="text" value="100"/>	<input type="text" value="57.295"/>	<input type="text" value="229.183"/>	<input checked="" type="checkbox"/> Degrees	<input type="text" value="10"/>
	Cnts/inch	Vel in/sec	Accel in/sec <sup>2</sup>		Radius inches
B	<input type="text" value="100"/>	<input type="text" value="10"/>	<input type="text" value="10"/>	<input type="checkbox"/> Degrees	<input type="text" value="1"/>
	Cnts/inch	Vel in/sec	Accel in/sec <sup>2</sup>		Radius inches
C	<input type="text" value="100"/>	<input type="text" value="10"/>	<input type="text" value="10"/>	<input type="checkbox"/> Degrees	<input type="text" value="1"/>

The Axis Motion Parameters define the scale, maximum feed velocities, and maximum feed accelerations for each of the six axis.

The first parameter is the axis's scale in counts/inch. For the example value of 100 shown, *KMotionCNC* will command the motion controller to move 100 counts for each inch of motion in the G Code Program. This value is always in counts/inch regardless of the units used in the interpreter. *KMotionCNC* will automatically perform any conversions.

The second parameter is the maximum allowed feed rate for the axis in inches/sec. Note that the G Code Interpreter Feed Rate is defined in inches per minute or (mm per minute) so be aware of the different time units. These are *maximum* feed rates for each axis. If a vector tool motion at a particular feed rate has any component velocity that exceeds the corresponding axis's maximum velocity, the feed rate for the vector will be reduced so that all axes remain at or below their maximum allowed velocity.

The third parameter is the maximum allowed acceleration for the axis in inches/sec<sup>2</sup>. The G Code Language has no provisions for specifying acceleration rates. Therefore the acceleration (and deceleration) along a vector used will always be the largest acceleration such that each axis's acceleration is at or below the specified limit.

The velocity and acceleration limits apply only to linear and circular feed motions (G1, G2, G3). Rapid motions (G0) use the settings in the motion controller (velocity, acceleration, and Jerk) to move each axis independently from one point to another (which is likely not to be a straight line). To change the speed of Rapid motions change the configuration settings in the motion controller.

Axes A,B,C sometimes are angular axes and are programmed to move angles of degrees rather than linear distances. If so select "Degrees" so that the axis moves in degrees regardless of the Inch or mm modes in GCode.

The best method for performing coordinated linear and angular combined motion is to use G93 Inverse Time Mode. This mode allows the CAD system to generate GCode that will cause the feed rate at the tool to always be at the desired feed rate based on the geometry of the system. However this requires a time (specified by its inverse) for each GCode block to be computed and included in the data stream. If Inverse Time GCode data is not available a Radius for each Angular Axis can be specified. This allows the Trajectory planner to convert angular motion rates to linear motion rates. This assumes that the tool will remain at a relatively constant radius from the rotation axis (ie. engraving on a cylinder). Whenever Degrees is specified with a non-zero radius then the Trajectory Planner will consider the motion for that axis to be at the equivalent radius and orthogonal to all other combined motions.

As an example for the settings shown above for Axis A the maximum linear Velocity and Acceleration rates are the same as X, Y, and Z assuming a 10 inch radius about the A Axis of rotation.

$$57.295 \text{ deg/sec} \times \pi/180\text{deg} \times 10\text{in} = 10\text{in/sec}$$

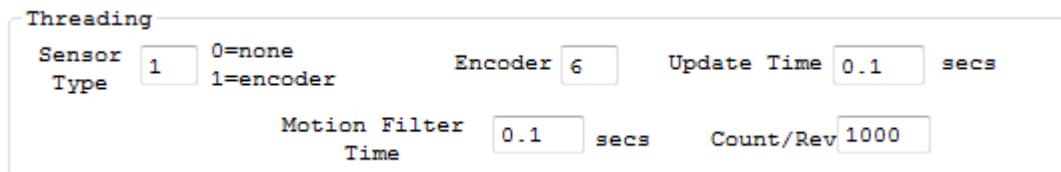

$$229.183 \text{ deg/sec}^2 \times \pi/180\text{deg} \times 10\text{in} = 40\text{in/sec}^2$$

The GCode sequence shown below will perform a G1 Feed a linear distance of 10 inches in both X and A. Because the X and A axis are assumed to be orthogonal the combined distance will be

assumed to be 14.1 inches total. At a feed rate of 60 ipm = 1 ips, the total Feed Time will be 14.1 sec (plus a small acceleration time).

G0 X0 Y0 Z0 A0
G1 X10 A57.295 F60
M2
```

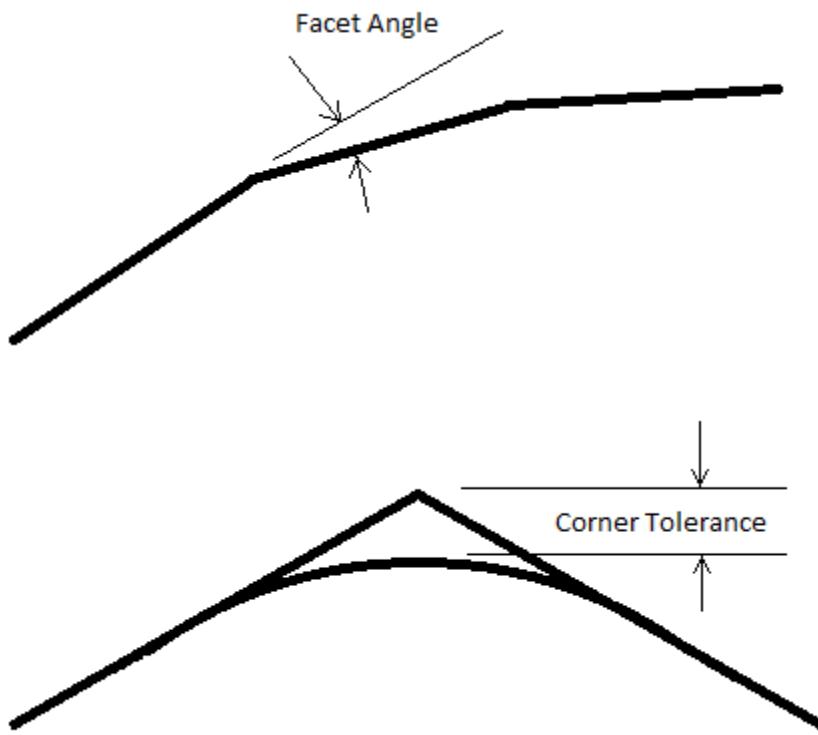

## ***Threading/Spindle Settings***

Spindle Speed measurement is also supported (Single Point Threading is under development). A quadrature encoder is required on the spindle. Specify the Sensor Type as 1 to enable the Spindle measurement. Configure the Axis Channel that is configured to read the encoder (Note this is not the encoder channel, rather it is the axis that has the encoder channel configured as its input). Specify the Update time, Tau, and counts/rev. See [here](#) for more information.

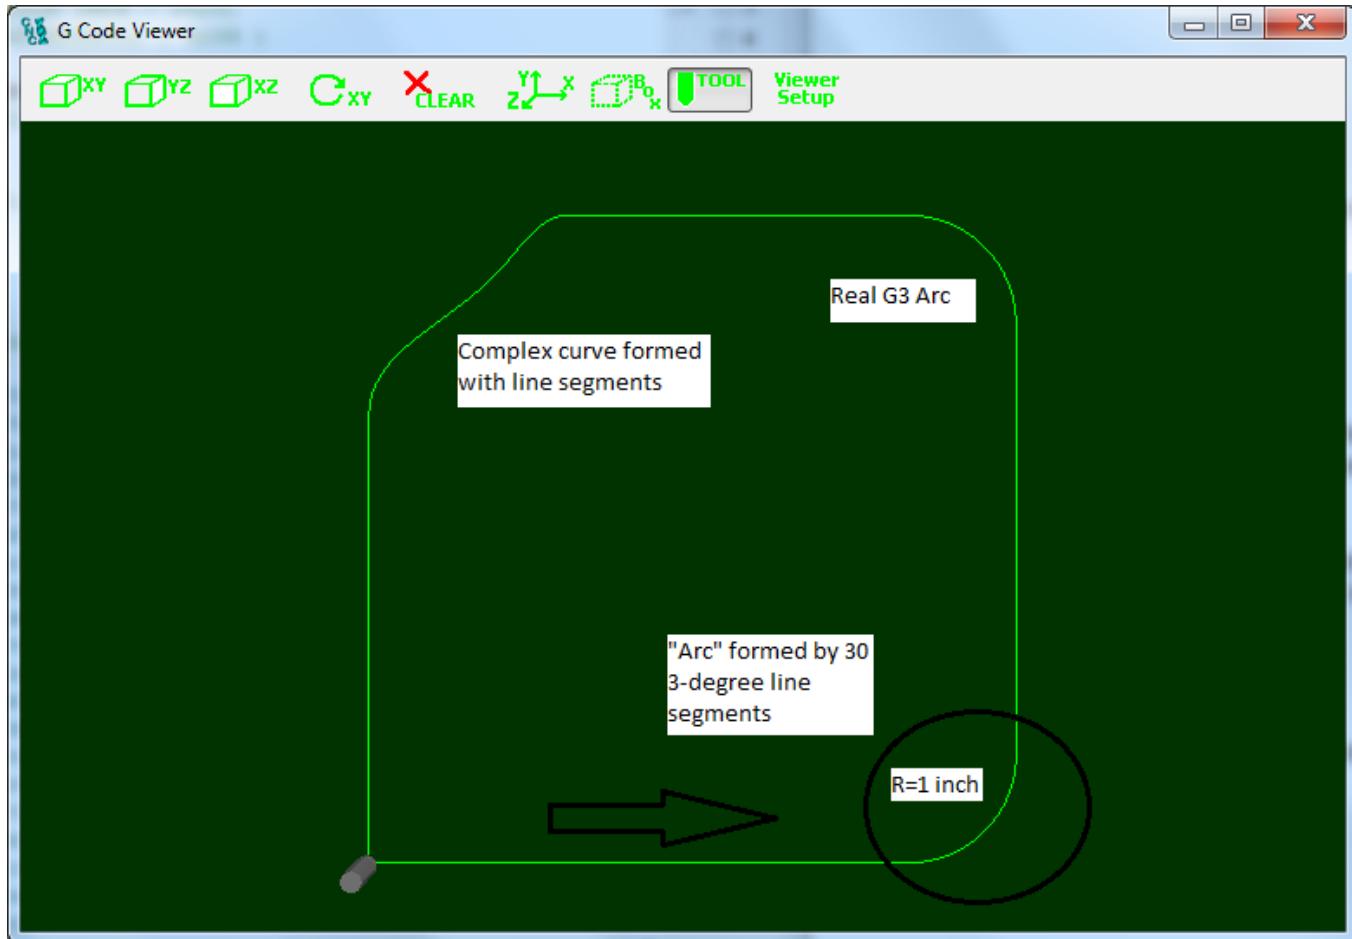

## ***Trajectory Planner Corner Rounding Settings***

The KMotionCNC Trajectory planner contains two parameters (Facet Angle and Corner Tolerance) that can be used to smooth paths generated by line segments in the GCode. Although shown below as 2D paths this smoothing applies for 3D paths as well. Standard GCode and many CAD systems do not support arcs in arbitrary 3D space so small line segments are typically used to define the 3D path. Facet Angles in the original GCode data that are less than the specified Break Angle (which are considered "small" and will not cause a motion stop) will be re-faceted with smaller line segments along a curve to have Facet Angles smaller than the specified amount. The new line segments will be placed along the largest arc that will not deviate more than the specified Corner Tolerance or consume more than 1/2 of the segment length. If no Corner Rounding is desired the Corner Tolerance can be set to zero.

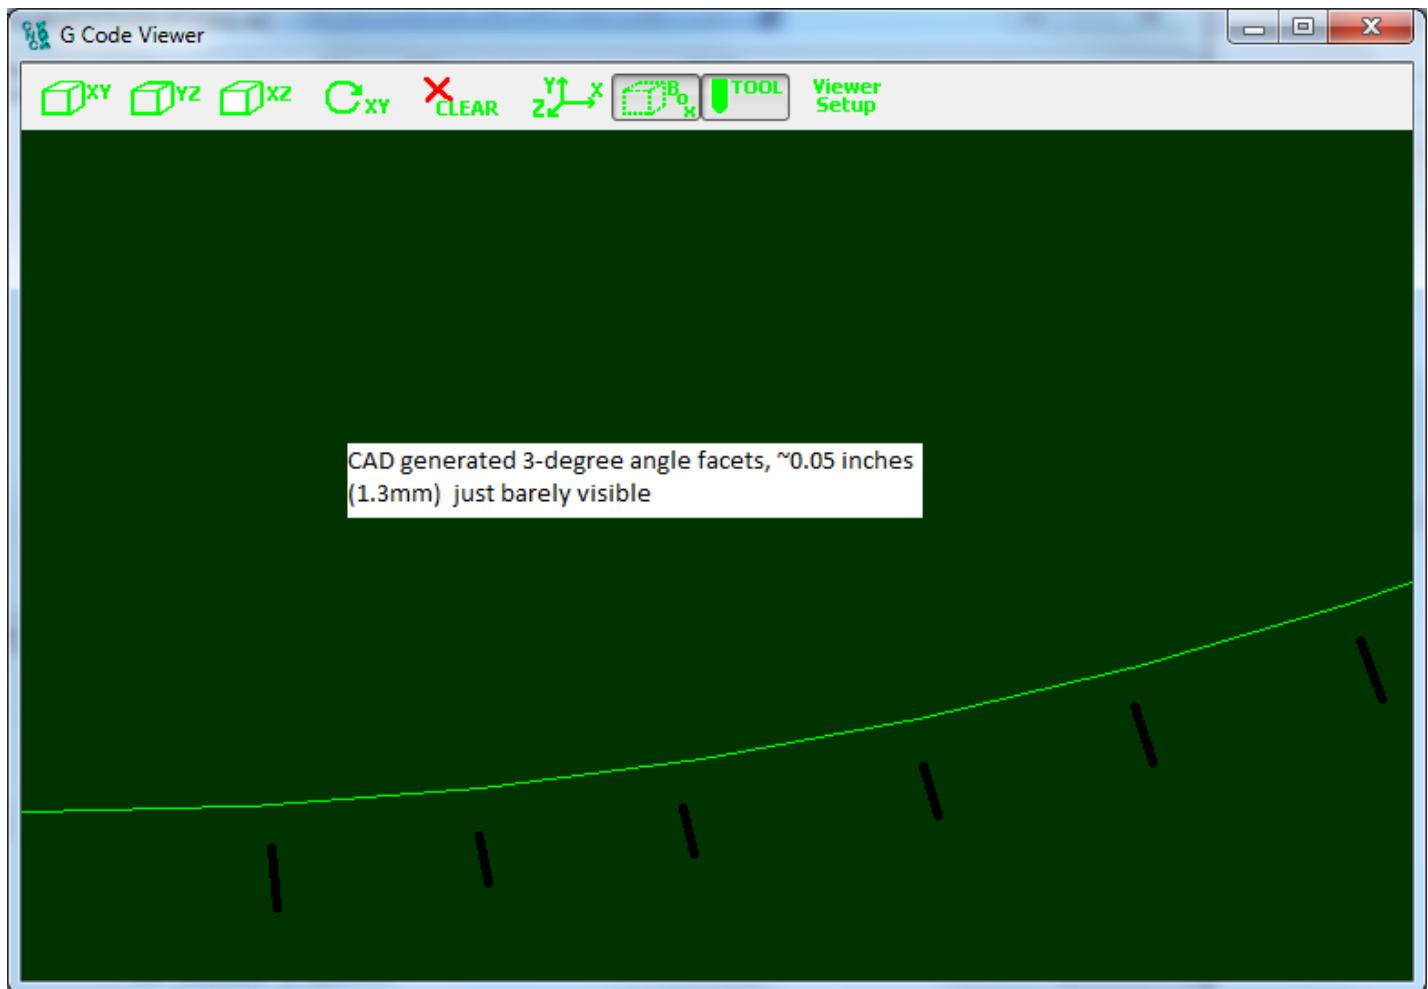

Shown below is an example motion path where the bottom right arc is formed by 30 line segments. Normally a simple arc could be specified but for test purposes it was created with 30 3 degree angle facets forming the 90 degree turn. The tests below were performed simulating a fairly high performance system with 30 in/sec<sup>2</sup> acceleration in both X and Y. The Gcode used can be downloaded [here](#).

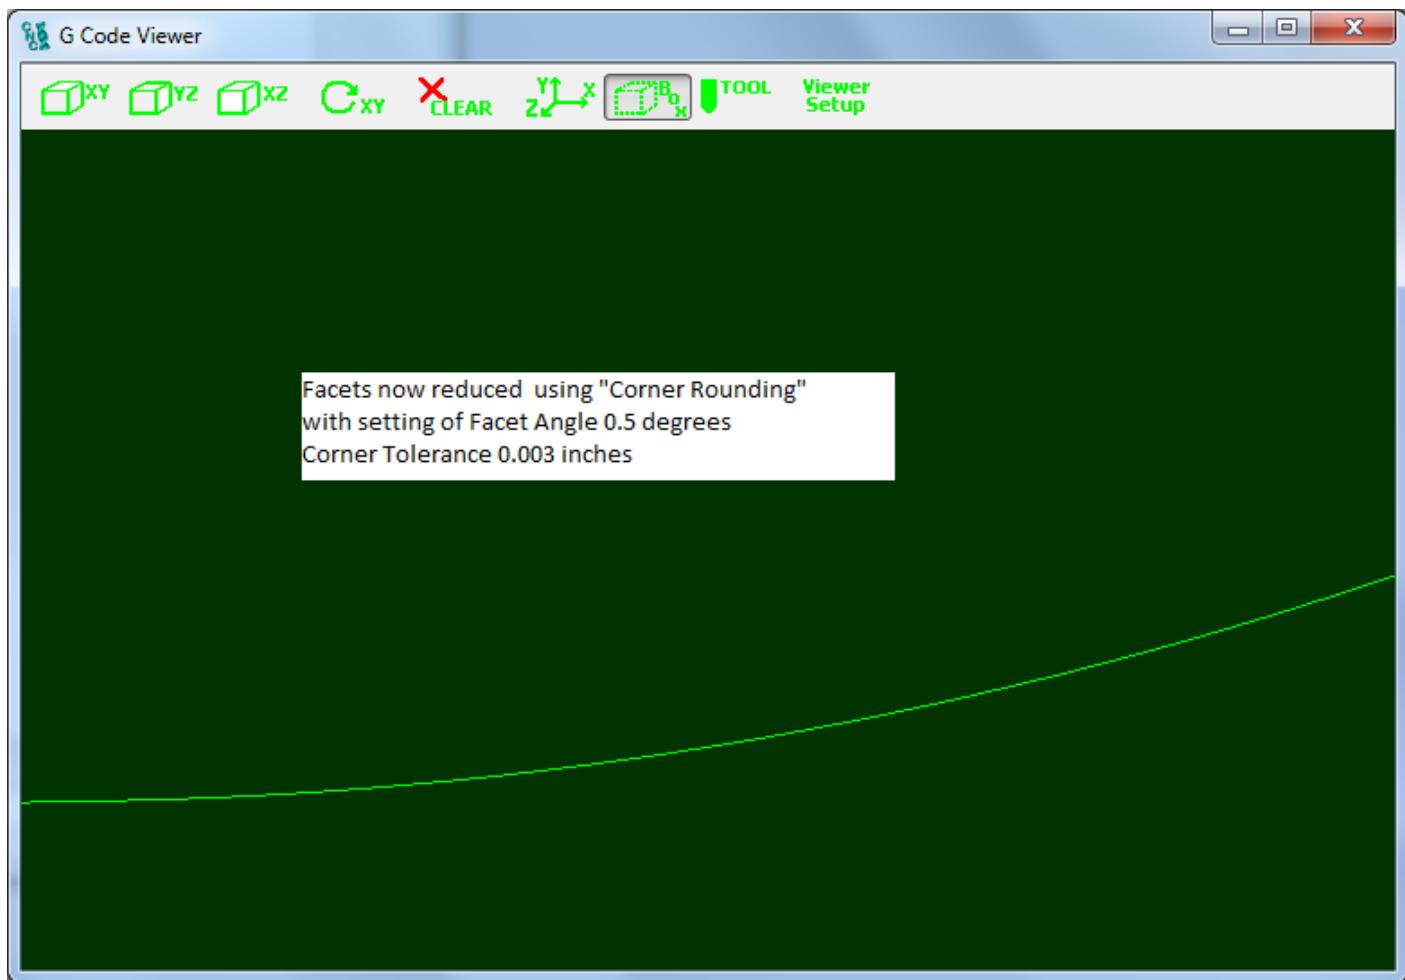

Here is the path Overview.

Notice the circled region of the path looks smooth, but when zooming in as shown below the 3-degree angle facets are just barely visible. This resolution is typically used to provide a reasonably smooth path without making the file size abnormally large.

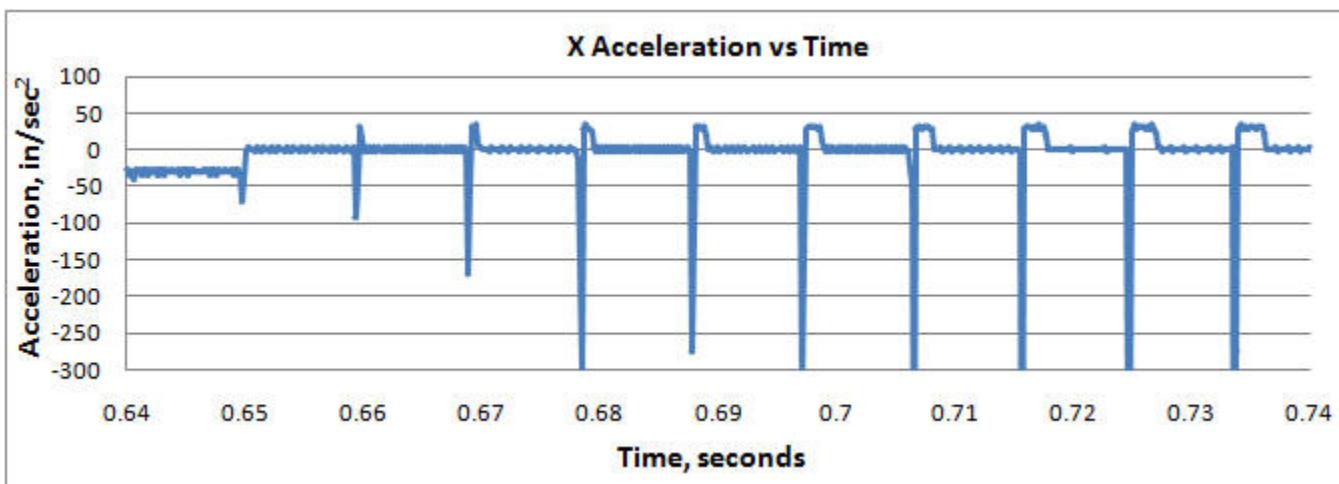

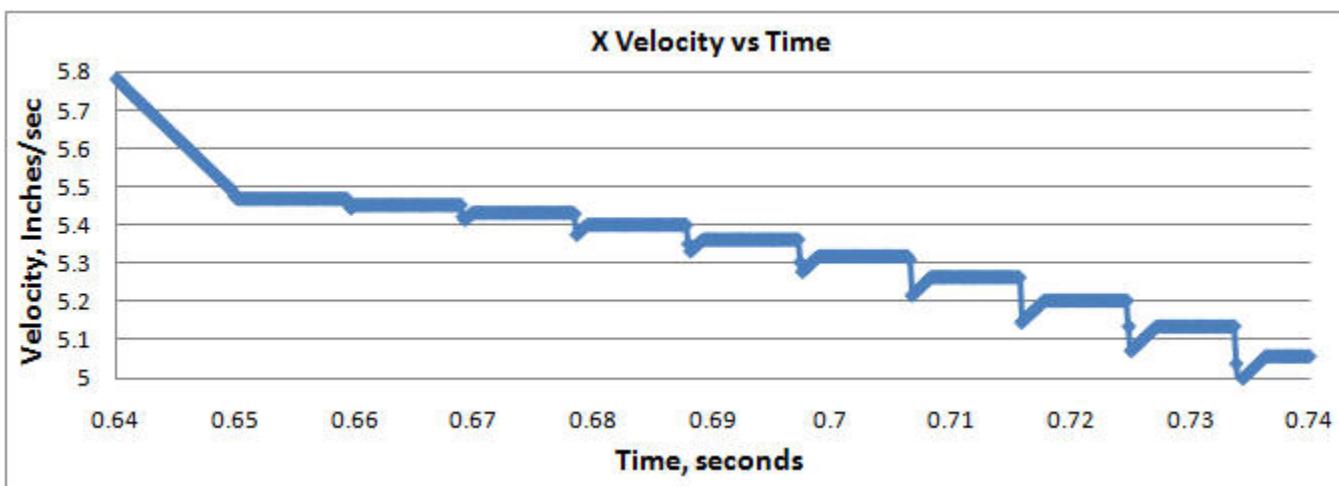

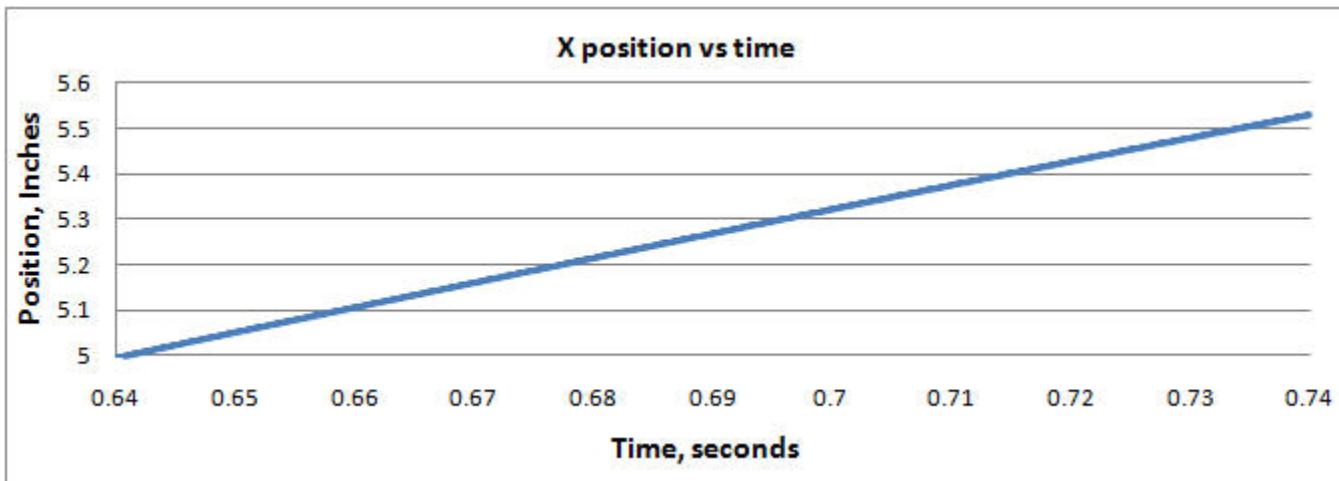

In the plot below the Corner Rounding is enabled and the facets are now reduced in size and form 0.5 degree angles that can now no longer be seen.

To see more clearly the improvement the X Axis motion was captured in real-time (180us sample rate) and plotted. From the position the Velocity and Acceleration were also computed and plotted.

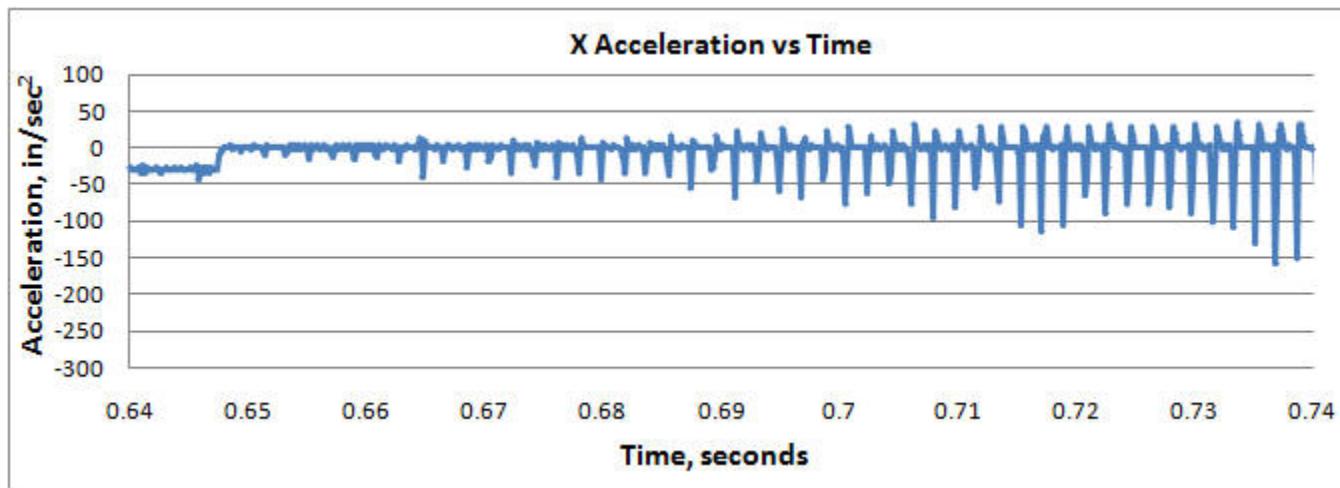

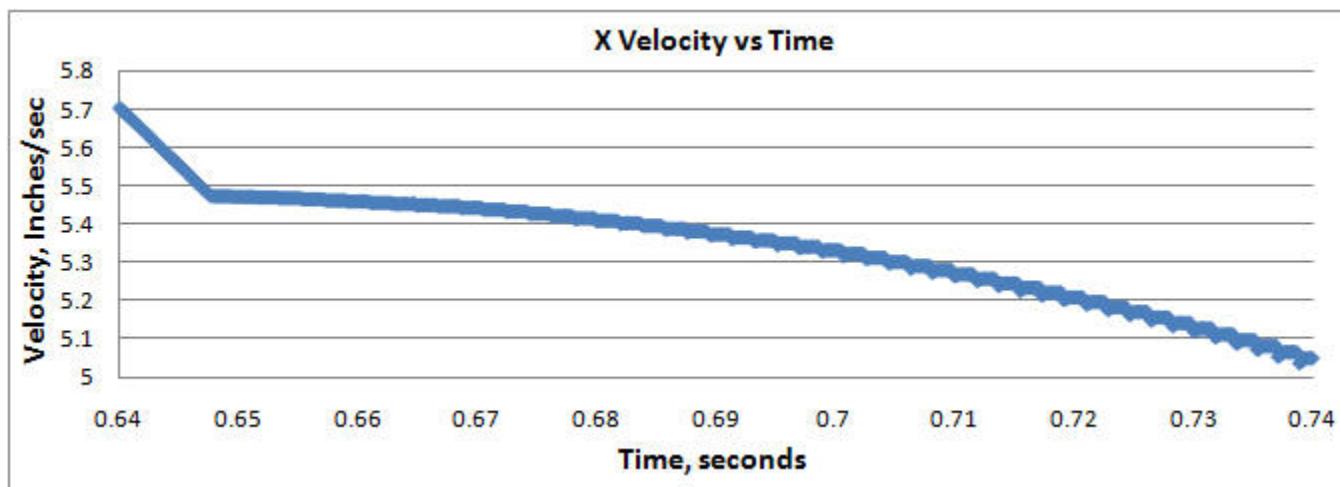

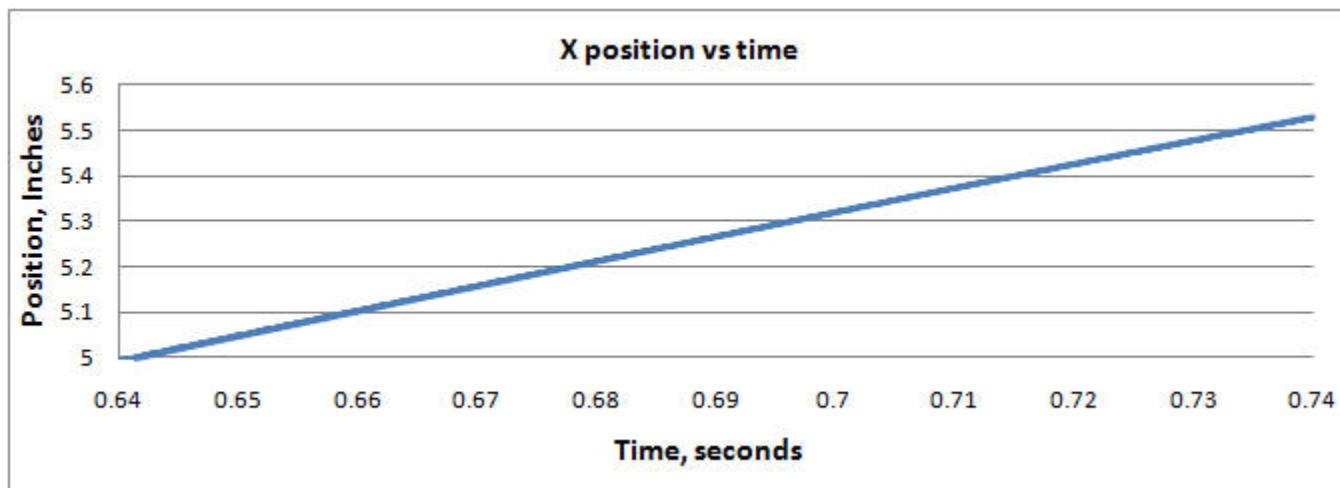

First the original captured motion X axis position, velocity, and acceleration vs. time through the original 3-degree facets with no corner rounding.

Note that the velocity plot has an odd shape for several reasons. At constant velocity the facet angle change causes the x velocity to drop while the y velocity increases, but since we are accelerating through the curve (because a more diagonal direction can make use of the increased (combined) acceleration of both axes) the velocity ramps up at the max acceleration toward the beginning of each facet. The programmed feed rate is 400ipm (6.67ips) but the speed is acceleration limited by the curvature of the path, hence the deceleration to ~ 5.5ips on the left as we enter the curve.

Now using the Trajectory Planner settings shown below. Notice the velocity is much smoother and the Acceleration is less Jerky.

Trajectory Planner							
Break Angle	5	degrees	Look ahead	3	seconds	Collinear Tolerance	0.0001 in
Corner Tolerance	0.003	in	Facet Angle	0.5	degrees		

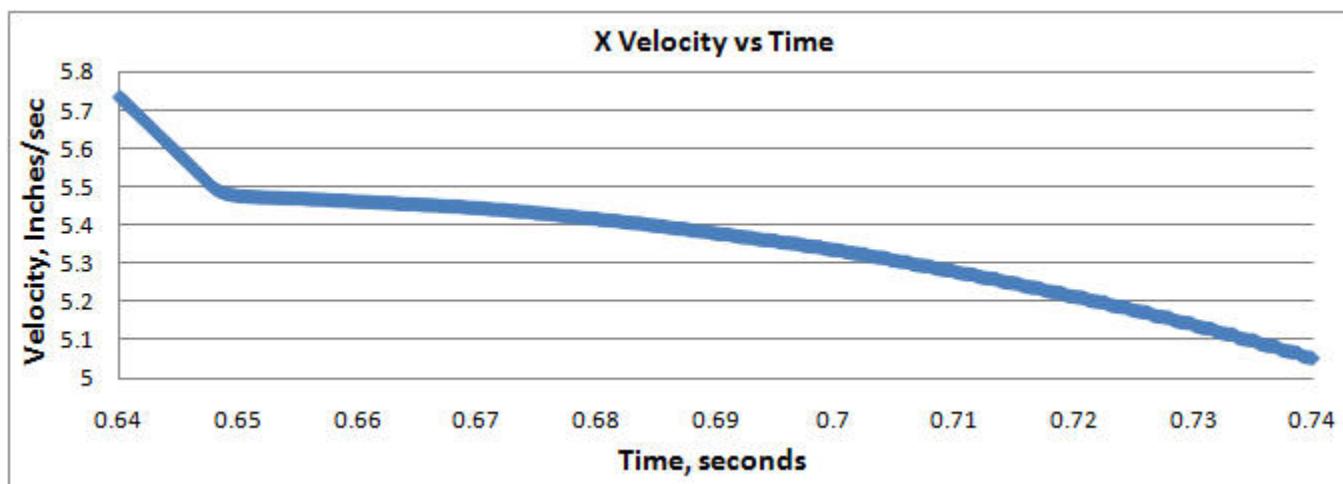

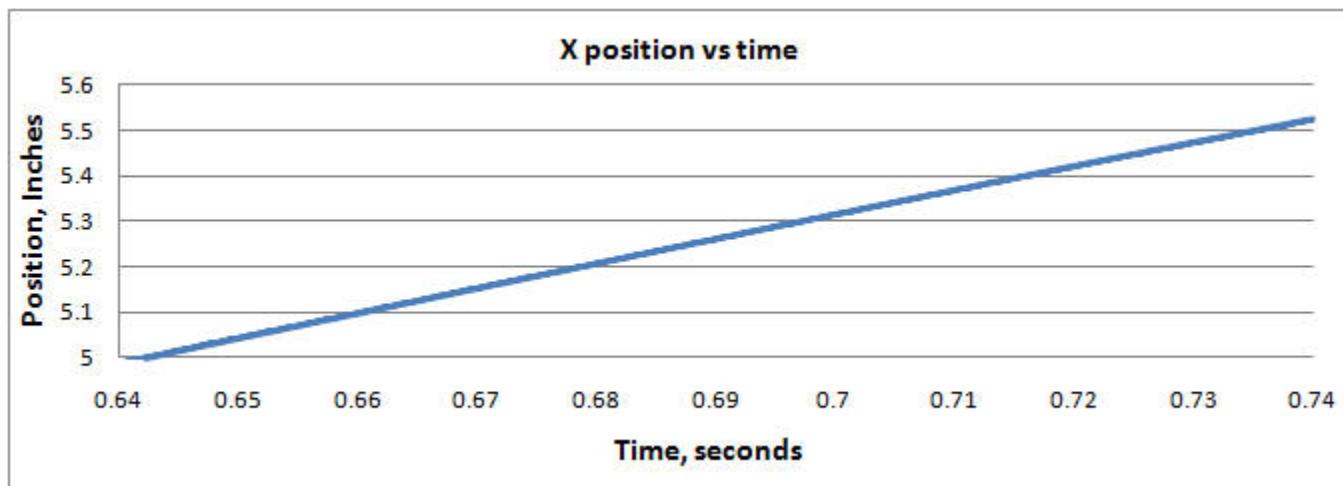

For still further motion smoothing an additional KFLOP feature can be used. A low pass filter can be applied to the output of the coordinated motion path.

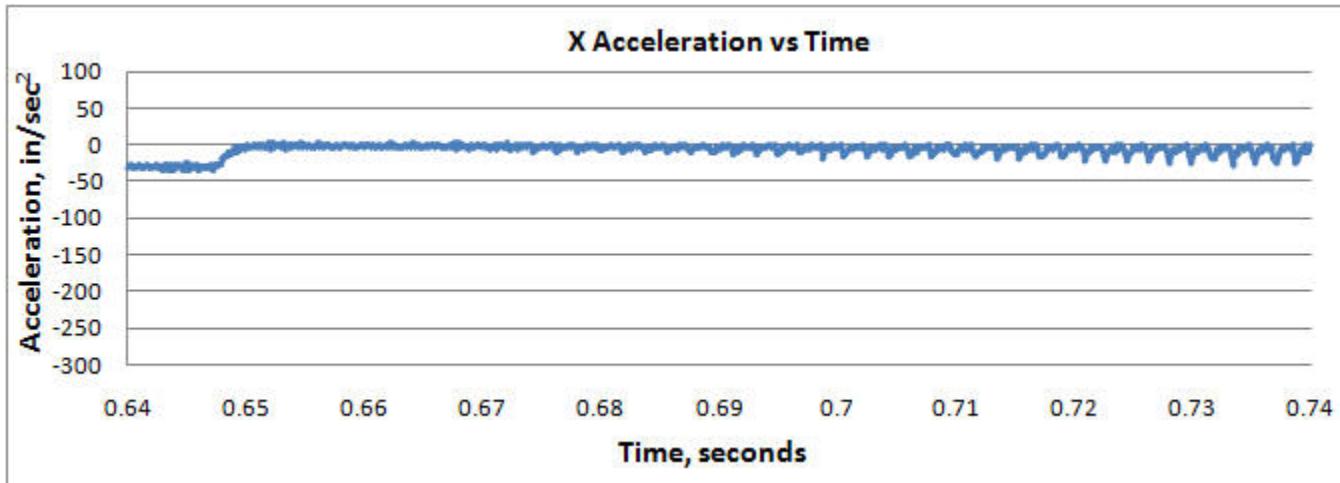

The Low Pass Filter will be applied to all axes of coordinated motion (up to 8) by setting the KLP coefficient within KFLOP. Currently a C Program must be used to set this global parameter.

To compute an appropriate coefficient from a time constant Tau in seconds use the formula  $KLP = \exp(-TIMEBASE/Tau)$  as shown below

```
#include "KMotionDef.h"
main()
{
double Tau = 0.001; // seconds for Low Pass Filter Time Constant
KLP = exp(-TIMEBASE/Tau);
printf("Tau=%f KLP=%f\n",Tau,KLP);
}
```

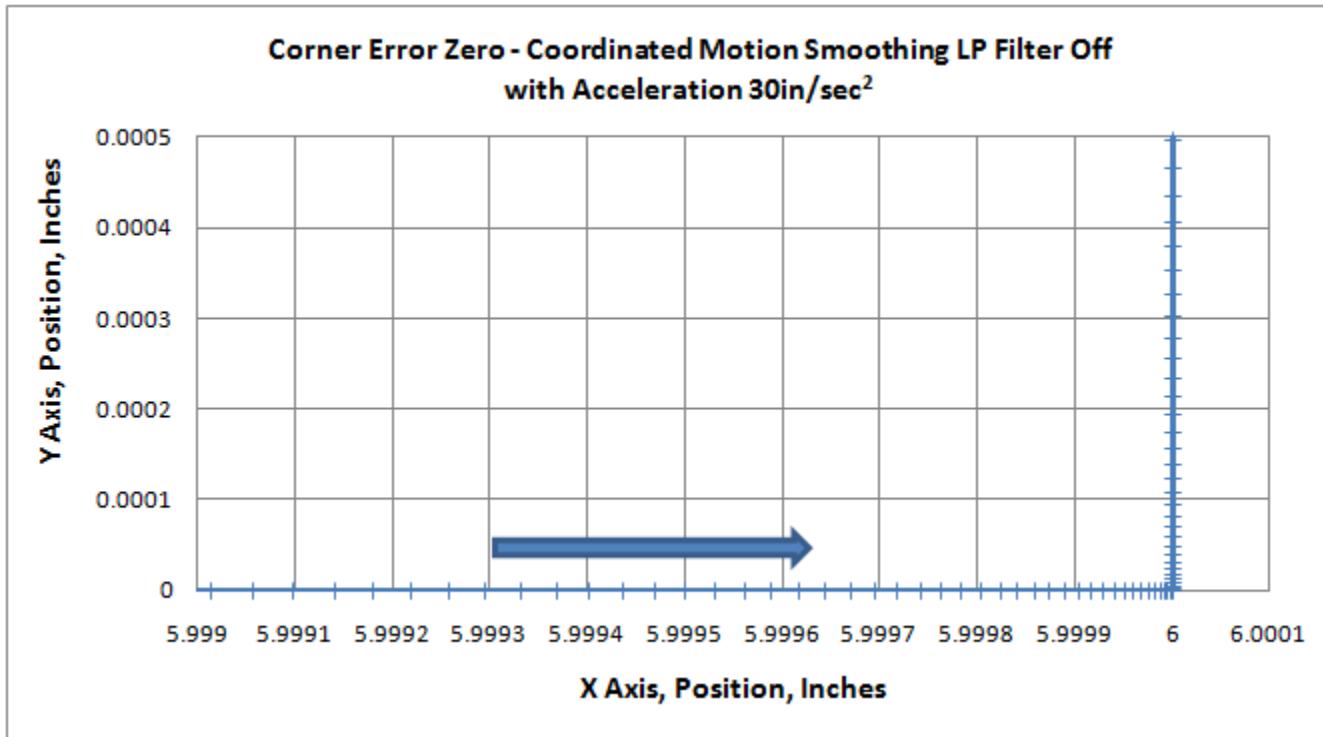

Note the Velocity and Acceleration plots are even smoother. A low pass time constant  $Tau = 1$  millisecond was used.

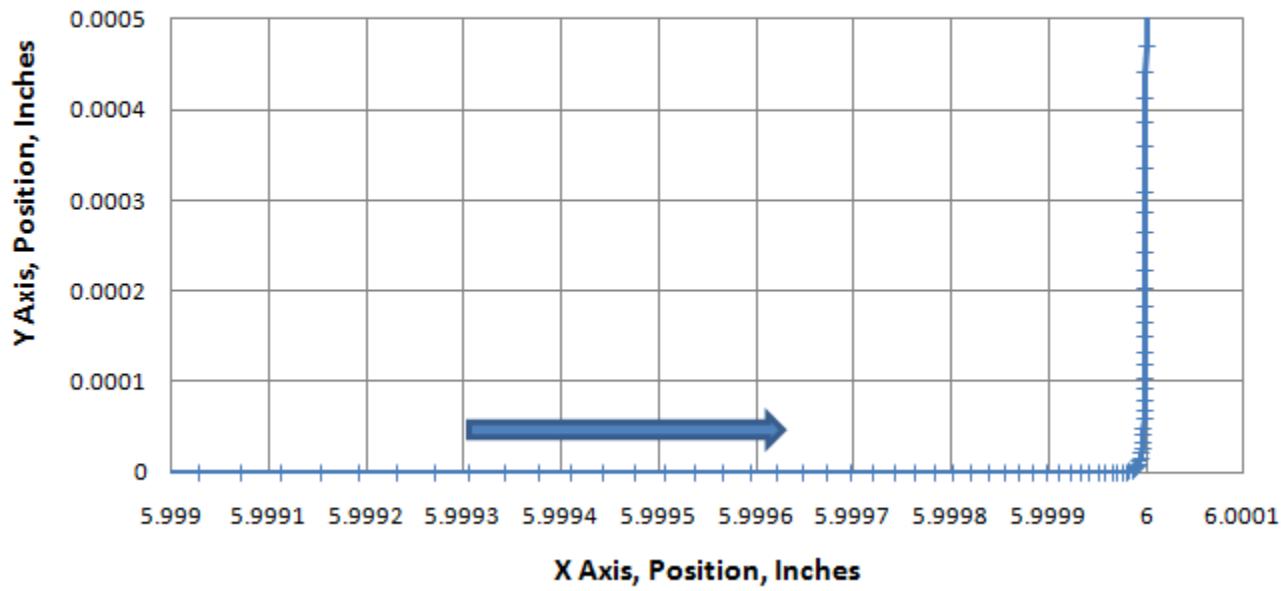

The disadvantage associated with low pass filtering of the trajectory is a potential lag in the commanded positions which may cause small path errors. The plots shown below show that a Low Pass Filter setting of 1 millisecond will be insignificant for most systems. A nearly worst case 90-degree angle with max deceleration on the X axis, followed by max acceleration on the Y axis are shown below.

The first case is captured with no Low Pass Filtering. Note a perfectly square corner. Each tick mark shows a captured 180us sample point.

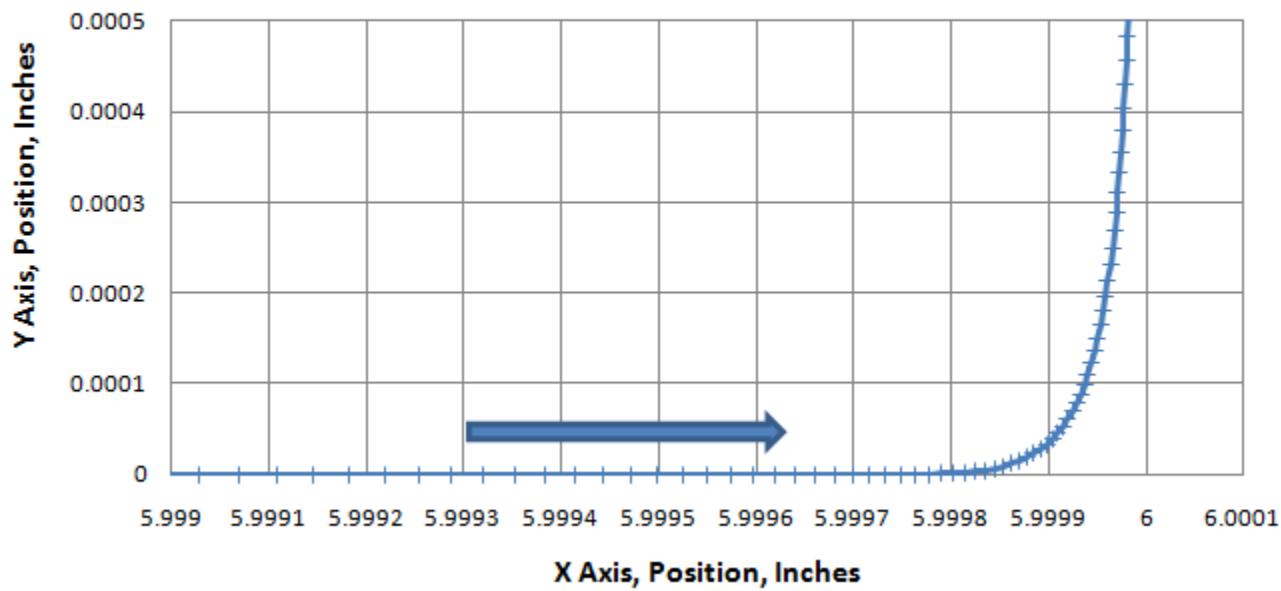

The case below is with 1 millisecond of filtering with a path error of ~ 0.01 mil (0.25um)

**Corner Error ~ 0.01mil - Coordinated Motion Smoothing LP Filter 0.001 seconds  
with Acceleration 30in/sec<sup>2</sup>**

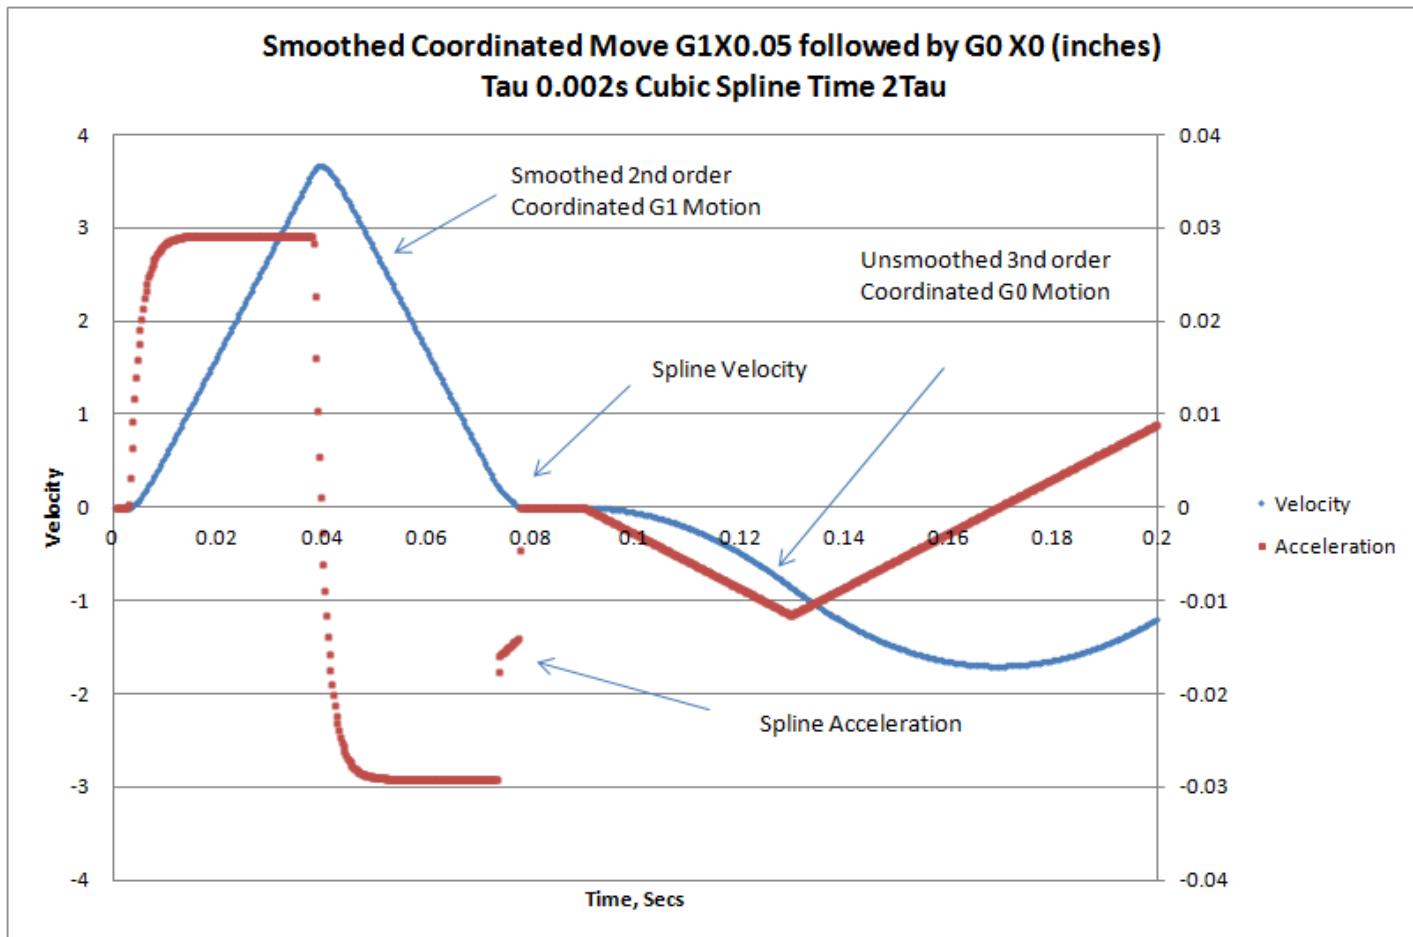

The case below is with 3 milliseconds of filtering with a path error of ~ 0.1 mil (2.5um)

**Corner Error ~ 0.1mil - Coordinated Motion Smoothing LP Filter 0.003 seconds  
with Acceleration 30in/sec<sup>2</sup>**

Because the Low Pass Smoothing introduces a small position lag the very end of the smoothed path will not be completed when the coordinated path is completed. To complete the path the final position and velocity of each of the coordinated axes are used to calculate a Cubic Spline to complete the final small motion. The Cubic Spline allows continuous velocity from the end of the smoothed path to the target position in a manner where the velocity also reaches zero at the target position. A Time duration of the Cubic Spline set at  $2\times\text{Tau}$  of the low pass filter provides a relatively constant deceleration to the Target.

## Controlling KMotionCNC from KFLOP

User KFLOP C Programs can request actions to be performed by the KMotionCNC Application running on the PC by setting various command codes into special persist(userData variables. The special userData variables are being continuously uploaded with the Bulk Status record that KMotionCNC requests at approximately 10 times per second to update the DROs and so forth. If a command code is uploaded, KMotionCNC attempts to perform the requested action, then changes the userData Command Value to a result code. Zero indicates success and a negative value indicates an error code (all commands are positive). So the typical process involves:

#1 - KFLOP stores command into a Persist Var to request an action

#2 - The command is uploaded to KMotionCNC with the next status request

#3 - KMotionCNC performs the action

#4 - KMotionCNC clears the Persist Var to indicate completion

#5 - KFLOP detects the command Var has been cleared to know the action was successful and complete

The Status uploads several Persist Vars which permits additional parameters to be uploaded with the command to KMotionCNC if required by the action to be performed. If extra parameters or data is required, then one of the uploaded parameters will specify where that data is located.

The number of UserData variables has now been expanded from 100 to 200 Variables and Variables 100-107 are the special vars constantly uploaded with bulk status. This is defined in the PC-DSP.h file as:

```
#define PC_COMM_PERSIST 100 // First Persist Variable that is uploaded
in status
#define N_PC_COMM_PERSIST 8 // Number of Persist Variables that are
uploaded in status
```

Currently supported actions include:

- EStop
- Halt
- Execute
- Single Step
- Set FRO
- Inc/dec FRO
- Set X,Y,Z,A,B,C DROs
- Push a User Defined Action Button
- Execute an M Code
- Display a Message Box
- Get/Set GCode #Vars

- Execute a MDI line of GCode

A new example called KFLOPtoPCCmdExamples.c is included which demonstrates how to invoke these actions from a KFLOP User C Program. The following helper functions are included in the example that simplify invoking the actions by setting the proper persist variables. They are:

```
// Trigger a message box on the PC to be displayed
// defines for MS Windows message box styles and Operator
// response IDs are defined in the KMotionDef.h file
int MsgBox(char *s, int Flags)

// put the MDI string (Manual Data Input - GCode) in the
// gather buffer and tell the App where it is
int MDI(char *s)

// Put a Float as a parameter and pass the command to the App
int DoPCFloat(int cmd, float f)

// Put an integer as a parameter and pass the command to the App
int DoPCInt(int cmd, int i)

// Pass a command to the PC and wait for it to handshake
// that it was received by either clearing the command
// or changing it to a negative error code
int DoPC(int cmd)
```

The Example code to make use of the helper functions is in the example as:

```
main()
{
    int Answer;
    double *pD = (double *)persist(userData;

    DoPC(PC_COMM_ESTOP);
    DoPC(PC_COMM_HALT);
    DoPC(PC_COMM_EXECUTE);
    DoPC(PC_COMM_SINGLE_STEP);
    DoPCFloat(PC_COMM_SET_FRO,0.25f);
    DoPCFloat(PC_COMM_SET_FRO_INC,1.1f);
    DoPCFloat(PC_COMM_SET_X,0.0);
    DoPCFloat(PC_COMM_SET_Y,0.0);
    DoPCFloat(PC_COMM_SET_Z,1.25);
    DoPCInt(PC_COMM_USER_BUTTON,3);
    DoPCInt(PC_COMM_MCODE,3);

    Answer = MsgBox("Hello World",MB_YESNO|MB_ICONEXCLAMATION);
    if (Answer == IDYES)
        printf("Answer is Yes\n");
```

```
else
    printf( "Answer is No\n");

MDI( "G0 X1.2 Y2.2 Z3.3");

// put 3 double values in the persist vars

pD[10] = 123.456;
pD[11] = 1000.0;
pD[12] = 999.9;

// transfer up to the GCode Vars
SetVars(100,3,10); // Upload 3 to GCode 100 from persist 10

MDI( "#100 = [#100 + 1]");

// read them back into different persist Vars
GetVars(100,3,13); // Download 3 from GCode 100 to persist 13

printf( "%f %f %f\n",pD[13],pD[14],pD[15]);
}
```

## ***MCodes with Parameters***

KMotionCNC allows MCodes 100-119 with parameters when configured to Execute a KFLOP User C Program. The P Q and R words in the GCode block will be downloaded to KFLOP's persist(userData variables before the C program is executed. The parameters will be placed into consecutive KFLOP variables as 32-bit floating point values starting with the variable specified in the MCode Configuration. Zero, one, two, or all three parameters may be specified in the GCode block (line). The order they are placed into the variables will always be in the P Q R order where any or all of the parameters will be omitted if they are not explicitly specified in the GCode Block. If no parameters are specified then the MCode number will be stored into the one Var specified.

### ***Example M Code Configuration***

### ***Example M Code Usage with all 3 parameters***

M110 P1.23 Q4.56 R-1

### ***Example C Code accessing parameters:***

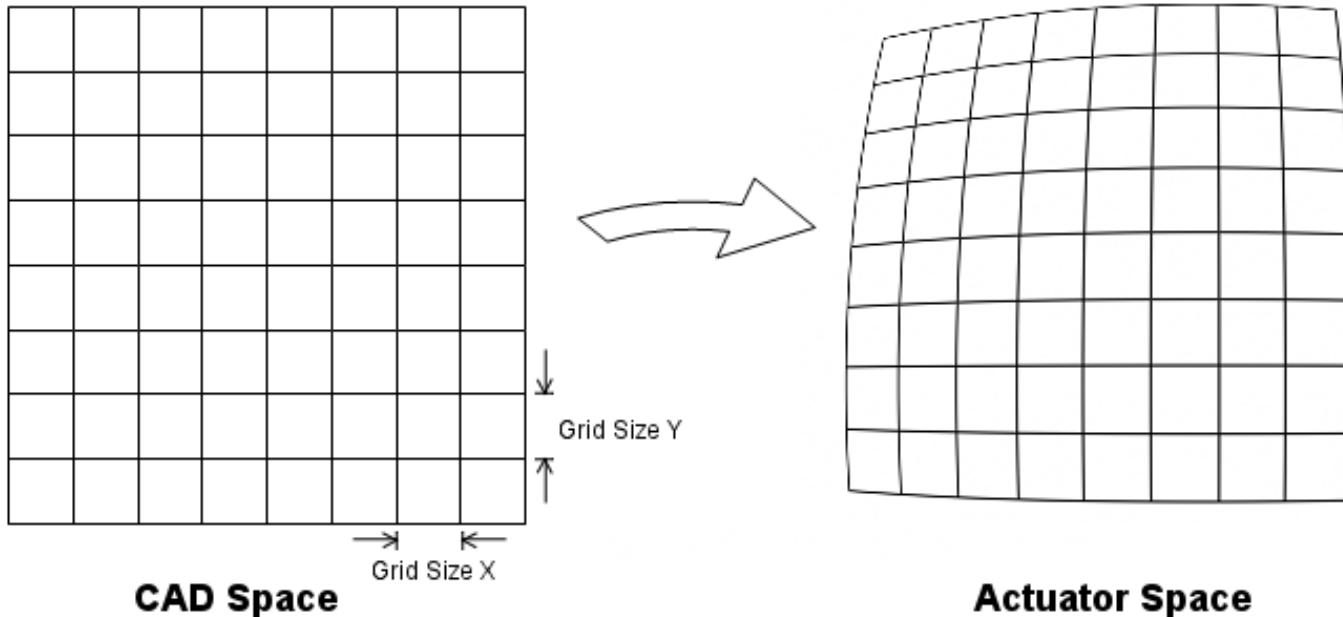

```
#include "KMotionDef.h"

main()
{
    printf("P = %f Q = %f R = %f\n",
        *(float *)&persist.userData[0],
        *(float *)&persist.userData[1],
        *(float *)&persist.userData[2]);
}
```

### ***Printed Result***

P = 1.230000 Q = 4.560000 R = -1.000000

## Geo Correction Table

The area of the CAD Space to be corrected is defined by a number of rows and columns and an XY Grid size. A CAD point falling within a grid uses a bilinear interpolation from the 4 points making up the grid region to map to actuator space.

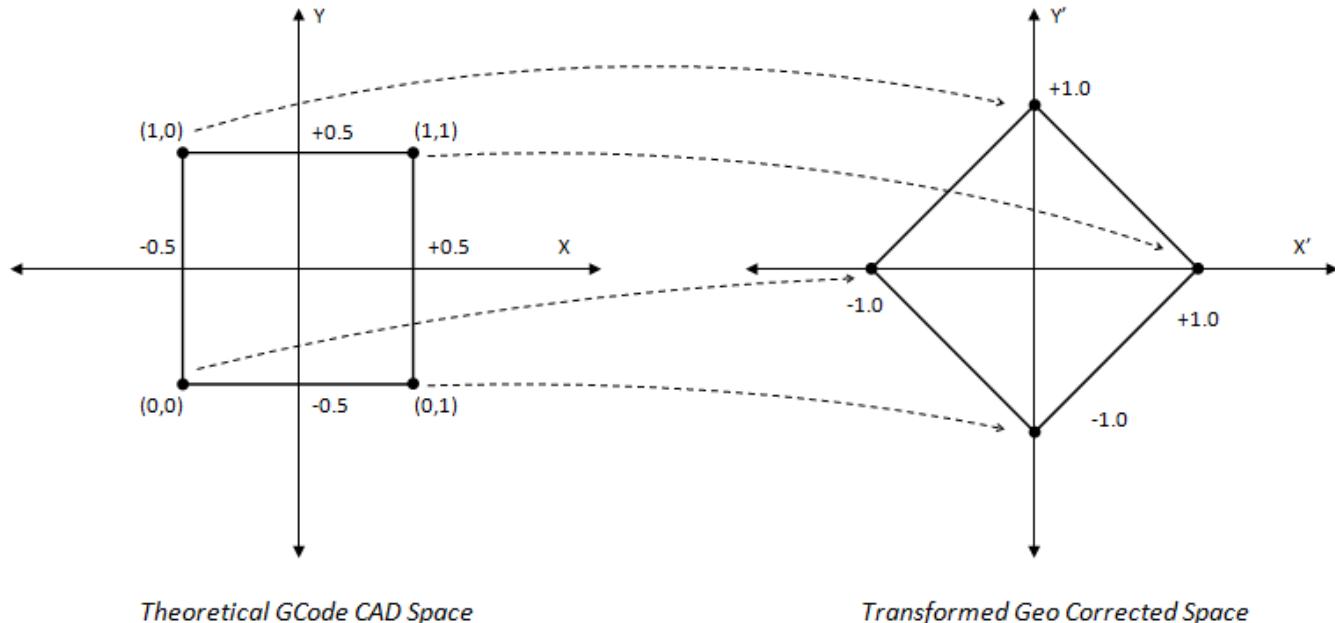

There is also a Z coordinate associated with each grid point. The mapping applies this as a Z offset in order to flatten the XY plane if necessary. If no flattening is required then the z values should all be specified as zero in the table.

Normally a Geo Correction Table is defined to be large enough to map the entire range of motion of the system. However, for points outside the range of the Table the closest grid region is extrapolated to form the result. The largest Table currently allowed is a 4000x4000 array.

When a Geo Correction Table has been loaded Arcs are automatically broken into small line segments internally where each segment's endpoints are Geocorrected into actuator space. This is necessary because an Arc in CAD space is unlikely to still be an Arc in Actuator Space. The Trajectory Planner [Collinear Tolerance](#) Setting is used to determine how small of line segments are used. Line segment lengths will be chosen small enough to not deviate from the true Arc by more than the Collinear Tolerance. For most systems a value of 0.001 inches should be used.

The smallest possible Geo Table consists of a single rectangle consisting of 4 points (2 rows and 2 columns). In this case the entire infinite CAD Space plane is mapped to the Actuator Space using a single set of transformation equations.

The Example below shows how the table can be used to form a simple transformation:

Theoretical GCode CAD Space

Transformed Geo Corrected Space

#### Example Transformation

$$X' = X + Y$$

$$Y' = X - Y$$

row	col	Y	X	$X' = X + Y$	$Y' = X - Y$
0	0	-0.5	-0.5	-1	0
0	1	-0.5	0.5	0	1
1	0	0.5	-0.5	0	-1
1	0	0.5	0.5	1	0

#### Corresponding Geo File

Simple 2x2 grid on CAD Space Grid Spacing of 1 inch in X and 1 inch in Y.

Then 4 grid points (row,col,X,Y,Z)

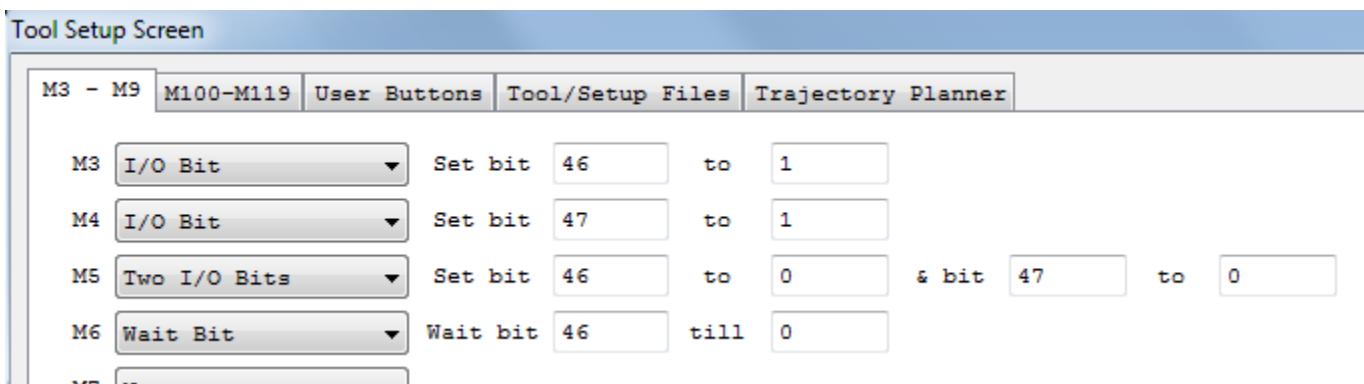

See file as <Install>\KMotion\Data\MeasurementsPlusMinus.txt

```
2,2
1,1
-0.5,-0.5
0,0,-1,0,0
0,1,0,-1,0
1,0,0,1,0
1,1,1,0,0
```

## Synchronous IO Commands Embedded in Coordinated Motion

KMotionCNC allows I/O operations to be embedded into the Coordinated Motion Buffer such that the IO commands are output synchronously (within 90us Servo Sample) with motion. (Buffered IO operations can also be inserted with Library calls from custom applications).

This example shows two MCodes configured to set bits I/O bits 46 and 47 high and also MCode M6 configured to wait for I/O bit 46 to be low.

A simple GCode Fragment shows the MCodes embedded within a continuous straight motion right at the point the motion reaches X=1.0.

The Trajectory Planner normally combines very collinear motion blocks together for smoothing and so forth. But in this case it is careful to not combine segments that cross a buffered I/O boundary.

```

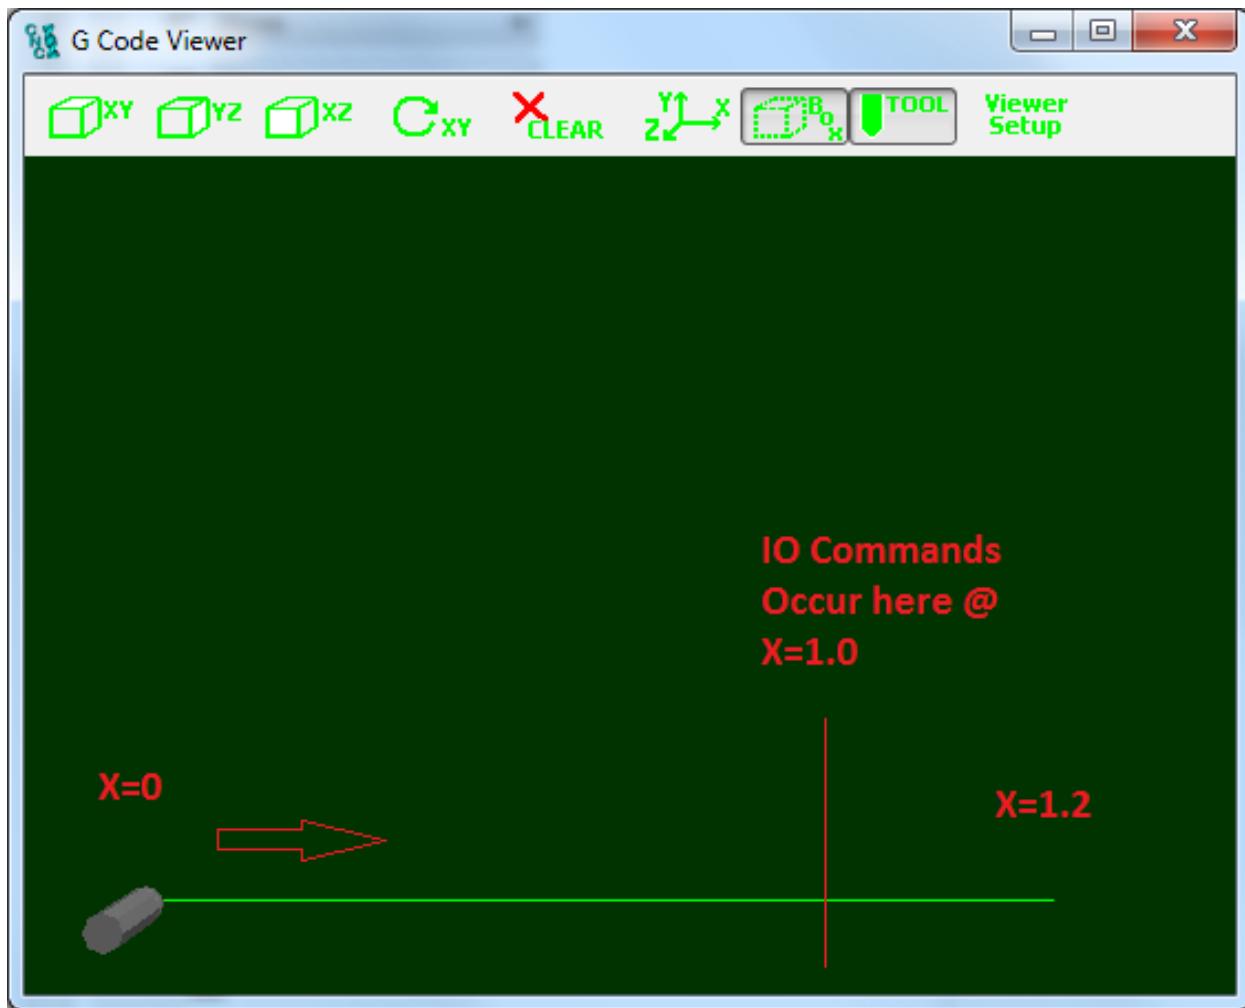

▶ G20

G1 X0.9
G1 X1.0
M3
M4
G1 X1.1
G1 X1.2
G1 X0
G1 Y0
M2
I

```

Buffered IO

Executing the GCode we can observe the IO bits 46 and 67 set high as the motion crosses X=1.0

Executing the GCode we can observe the IO bits 46 and 67 set high as the motion crosses X=1.0

The GCode below demonstrates a right-triangle motion path with the I/O commands inserted at a corner.

```

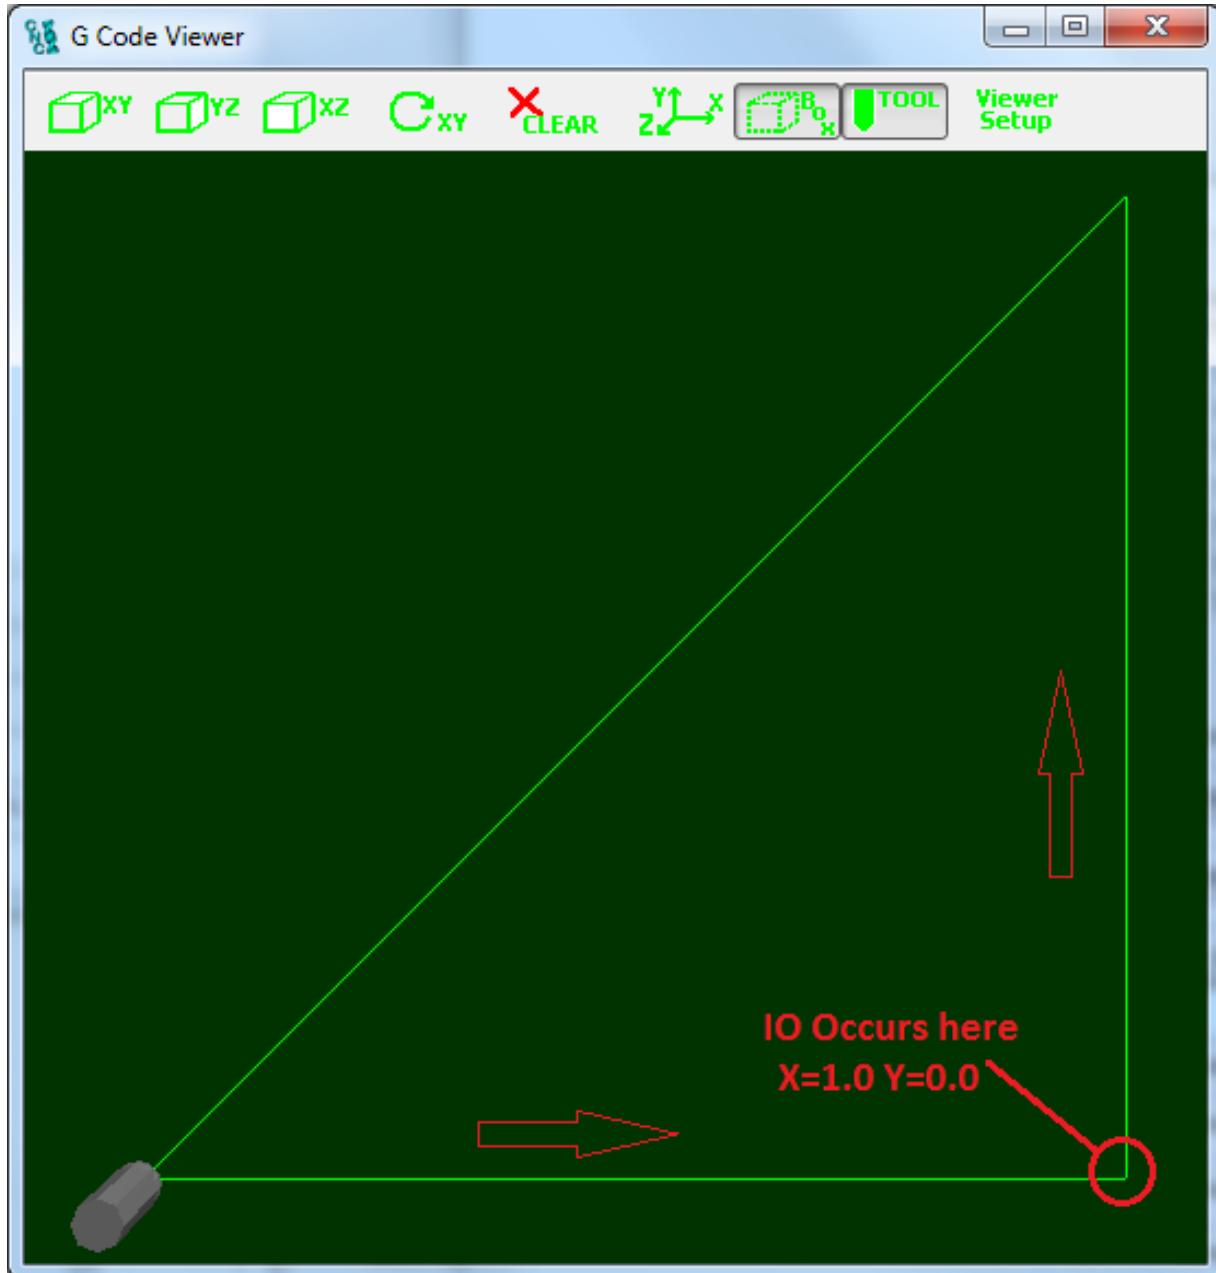

▶ G20
G0 X0 Y0 Z0
F60
G1 X0.8
G1 X0.9
G1 X1.0
M3
M4
G1 Y0.1
G1 Y0.5
G1 Y1.0
G1 X0Y0
M2

```

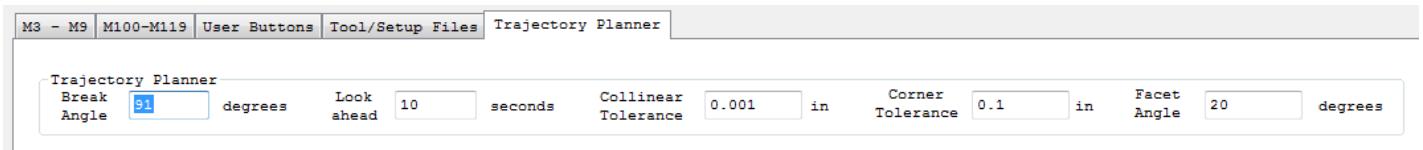

With Trajectory Planner Break Angle set to 10 degrees (which is less than 90 degrees) a full stop will occur at the corners.

In this case the IO switches where the instantaneous stop occurs at a corner.

To demonstrate what happens with corner rounding an exaggerated corner rounding example is shown below. With a Break Angle greater than 90 degrees a stop will not occur at the corner. Also a large radius (0.1 inches) and large facet angle (20 degrees) corner rounding is configured.

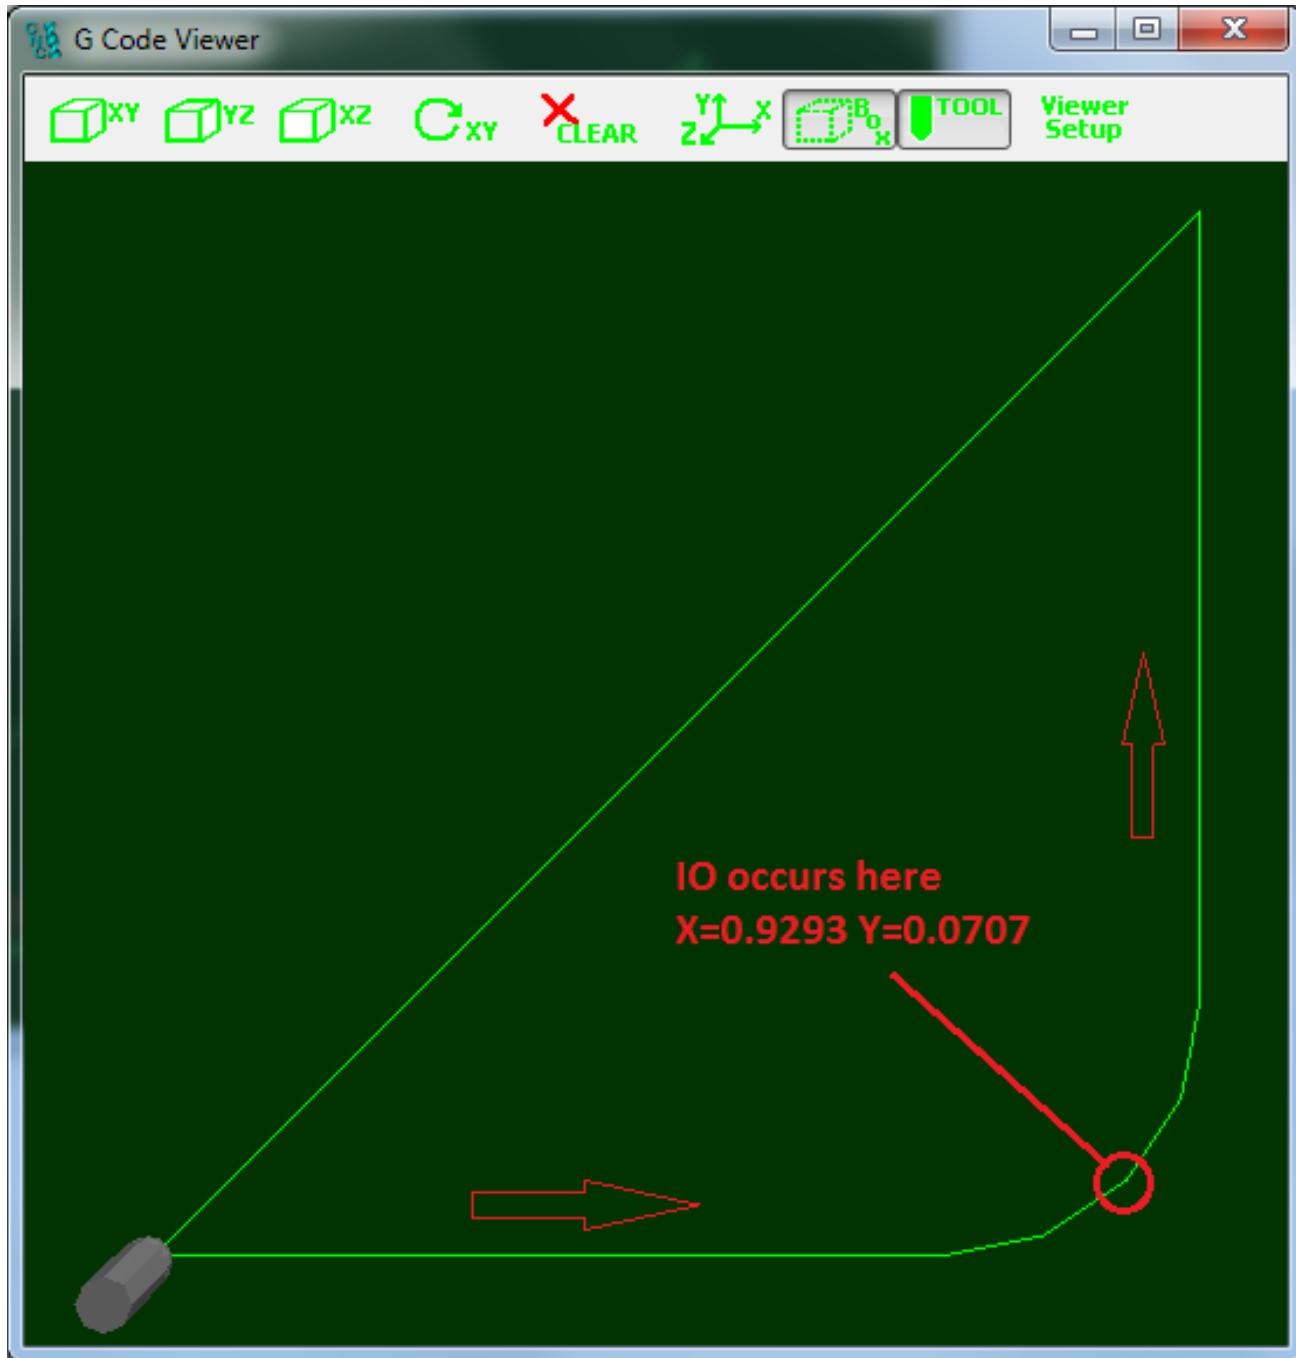

To observe exactly what happens we use the KFLOP C Program shown below to real-time capture the XY position when the IO occurs (XY resolution is 10000 counts per inch).

```
#include "KMotionDef.h"

main()
{
    int New,Last=ReadBit(46);
    for ( ; )
    {
        New = ReadBit(46);
        if (New != Last)
        {
            Last=New;
            printf("X=%f Y=%f\n",ch0->Dest/10000.0,ch1-
>Dest/10000.0); // send message to console
        }
    }
}
```

The captured position is printed as:

X=0.929315 Y=0.070748

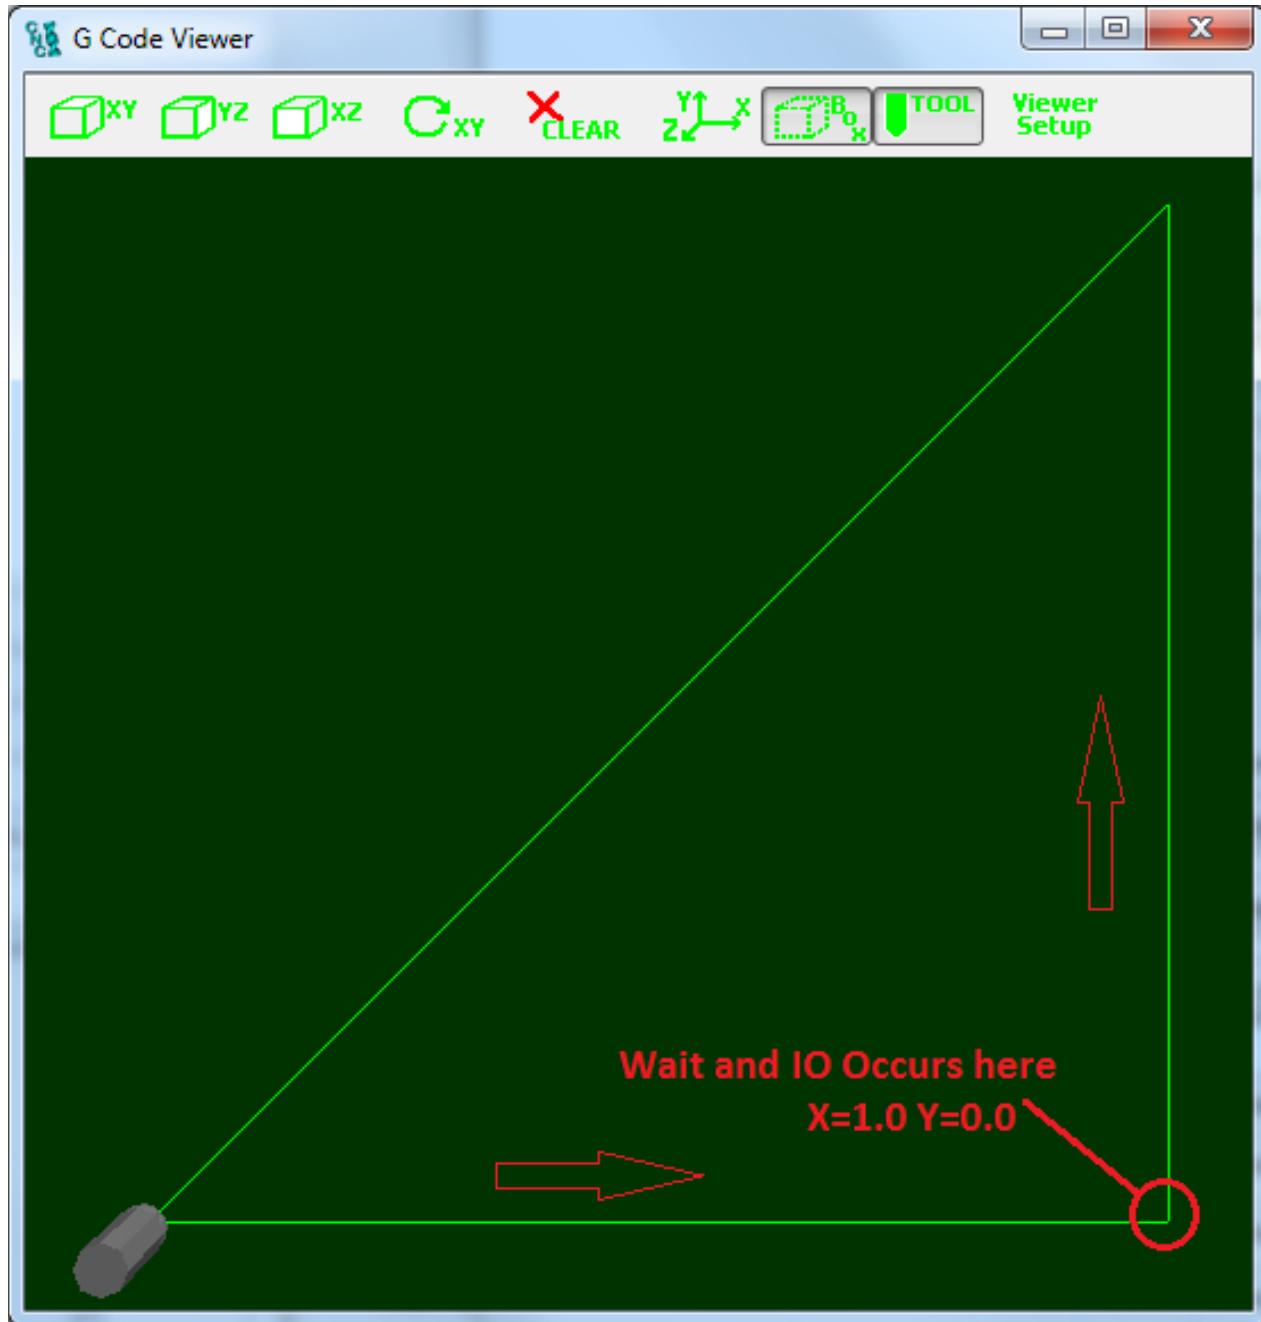

In addition to embedding outputs into the motion stream, waits for inputs can be embedded. This is inserted as a buffered [WaitBitBuf](#) command. When executed if the specified bit is false the motion will stall at that point until the input becomes true. There is a similar command [WaitNotBitBuf](#) that will stall until the input becomes false. MCodes can be configured to insert these commands. Although Wait commands can be inserted anywhere in a motion path it normally is only useful to place them at locations where the motion stops. Such as the very beginning of a path or at a corner where motion comes to a stop. Otherwise an instantaneous stop will occur without any

acceleration. Wait commands are useful when motion must proceed instantly on command. This is possible because the motion has already been Interpreted, planned, downloaded, and commanded to execute ahead of time. See the example GCode below where a wait has been inserted at a corner.

```
► G20

```

The plot below shows where the wait will stall execution if the specified bit is false.

# KMotionCNC Spindle Control

[Overview](#)

[Basic Configuration](#)

[User Program Configuration](#)

[CSS - Constant Surface Speed](#)

[Step-by-step Recap](#)

[Video](#)

[Configuring an Axis to Control a DAC open Loop](#)

## Overview

KMotionCNC allows the User to configure how the Spindle is to be controlled. Four basic actions that need to be defined are:

M3 - Turns on the Spindle in a CW direction

M4 - Turns on the Spindle in a CCW direction

M5 - Turns off the Spindle

Snnnn - Sets the desired RPM or Constant Surface Speed in feet/min or meters/min

To configure what action is to take place for each of the four functions the Tool Setup must be configured to either do the operations directly, or by invoking a KFLOP User C Program.

For the most basic cases where only one or two control IO bits are required for On/Off/Direction the IO operations can be configured directly. If Speed can be controlled by simple open loop scaling/limiting of a DAC output then speed control can also be configured directly.

For more complex cases and to allow control of virtually any type of Spindle, through any type of interface, KMotionCNC can be configured to invoke User programs to perform the four tasks listed above. Spindles might need to be controlled in a variety of different ways: Open Loop, Closed Loop, DACs, PWMs, Step/Dir, ModBus, Rs232, etc... Although this requires a small program to be written, it provides maximal flexibility and full control to the system designer. Usually with only a few lines of code the desired task may be performed. Common examples are provided.

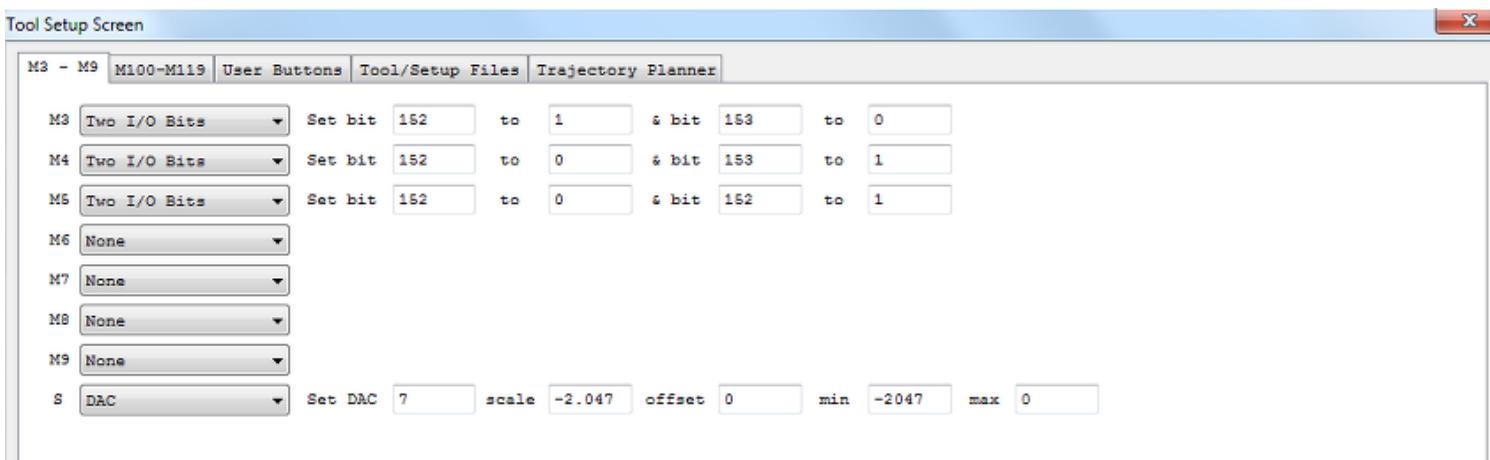

For G96/G97 - CSS (Constant Surface Speed) an additional program is required to run continuously in KFLOP which changes spindle speed continuously as a function of X position (radius). See the CSSJog.c example.

If a quadrature encoder is installed on the spindle it may be used for Spindle Speed Measurement and Display. See the Threading Configuration described [here](#).

## Basic Configuration

For basic configurations where the spindle CW/CCW/OFF can be controlled with one or two IO bits (normally Kanalog Relay Driver or Opto Outputs) and with speed control from a Kanalog DAC then no C programming is required. An example configuration is shown below. Note the S action is mapped to Kanalog DAC #7 with a negative scale of -2.047. Kanalog DAC outputs are inverting such that negative DAC counts result in a positive voltage. The assumption in this case is that an S value of 1000RPM would correspond to -2047 DAC counts or +10V. And the allowed range is from -2047 to 0 counts (0V to +10V).

An additional advantage to using I/O bits rather than C Programs is that they I/O commands will be embedded within the motion stream and will occur synchronously with the motion and without any pause in the motion. This is especially useful for faster systems with Lasers/Engravers/Extruders instead of a traditional Spindle. For more information on buffered IO commands see [here](#).

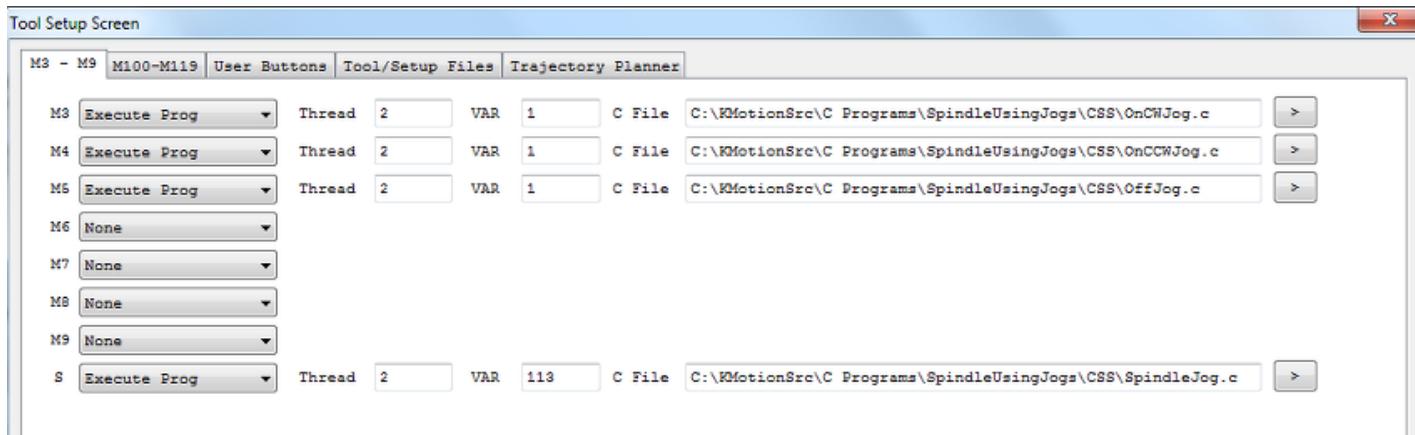

## User Program Configuration

For more advanced functionality User C Programs may be assigned for each of the spindle actions. For systems that have a spindle that can be controlled with an axis channel the C Programs listed below can be used directly with little or no modification. Note if your Spindle speed is controlled by a DAC an Axis channel can be configured to output open loop to a DAC, see [here](#) for how. This assumes that axis channel has already been configured much like the other axes in the system and can be moved using Axis Jog Commands. Spindles such as this are types that can be driven like a servo with feedback, or as an open loop Step/Dir drive. The only requirement is that a KFLOP axis channel can be used for control. This also allows acceleration (and Jerk) to be controlled by the axis channel for smooth speed changes.

The example configuration below shows the four spindle tasks assigned to four C programs. Each of the programs run temporarily to perform their function and should never execute concurrently so each can use the same Thread. See [here](#) for more information on Threads. M3, M4, and M5 do not pass any parameter so the VAR should be assigned to an unused Variable such as #1. For S

the speed value is passed in the VAR parameter. If G96/G97 CSS is to be used then the same VAR should be used as the G96 speed is passed. This VAR number is defined in PC-DSP.h as

```
#define PC_COMM_CSS_S 113 // S speed setting in inches/sec
```

In most cases the four C programs can be used without any modification. The programs all include a common file called MySpindleDefs.h that contain settings that are likely to require customization for any particular system. The file and parameters are defined and described below. Each of the four C programs includes this file with an include statement of: #include "MySpindleDefs.h". This should be placed immediately after the #include "KMotionDef.h" (which includes and defines all the standard KFLOP definitions).

Some Spindle controls/interfaces can accept a positive and negative command to drive in CW and CCW directions. Others require inputs (relays) to switch the directions and the speed is always set as a positive command. If your system is capable of accepting positive and negative commands then define

**USE\_POS\_NEG\_VOLTAGE** as 1 otherwise define it as 0.

### MySpindleDefs.h

```
#define SPINDLEAXIS 6 // Axis Channel to Jog to rotate Spindle
#define FACTOR (1000/60.0) // to convert RPM to counts/sec (counts/rev / 60.0sec)
#define SPINDLECW_BIT 154 // bit to activate to cause CW rotation
#define SPINDELCCW_BIT 155 // bit to activate to cause CCW rotation
#define SPEEDVAR 99 // global persistant variable to store latest speed
#define STATEVAR 98 // global persistant variable to store latest state (-1=CCW,0=off,1=CW)
#define KMVAR PC_COMM_CSS_S // variable KMotionCNC will pass speed parameter (113)
#define USE_POS_NEG_VOLTAGE 0 // 0 = output Magnitude, 1 = output positive and negative speed
```

These C Programs (located in the <Install Directory>\C Programs\SpindleUsingJogs\CSS directory) are written in a manner to handle a common issue with Spindles which is that a Speed change while the Spindle is commanded off should not be immediately applied. The four programs use two global variables to maintain the latest state and speed. This allows a speed change (when off) to be delayed until the spindle is turned on, but also be applied immediately if already on. In the example above VARs 99 and 98 are used for this purpose.

## CSS – Constant Surface Speed

Constant Surface Speed allows a lathe cutting tool to maintain a constant linear rate regardless of the current radius (or diameter) as the spindle RPM is continuously adjusted as a function of the radius.

Here is a simple GCode Program that uses G96 CSS mode

```
G90 G21          (Absolute mm)
G00 X50.8 Y0 Z50.8 (Rapid to starting position)
G96 M3 D2500 S159.6 (CSS should be 1000RPM at R=25.4mm)
G1 X2.54 Z25.4 F350 (Change X - radius)
G1 X50.8 Z0
G1 X2.54 F5000      (Change X - radius faster)
G1 X50.8 Z0
G1 X2.54          (Change X - radius faster)
G1 X50.8 Z0
M05              (Spindle off)
G0 Z50.8
G97 M3 S500        (Run at normal RPM Mode)
G4 P3
M2
```

G96/G97 CSS requires some additional C Program functionality to be running within KFLOP. When KMotionCNC decodes a G96 command to enter CSS mode it does so by setting a number of VAR parameters within KFLOP. A program continuously running within KFLOP will detect the CSS mode and set the Spindle RPM as a function of the X axis position (radius) and requested surface speed. The five variables set by KMotionCNC to control CSS are listed in the shared header file PC-DSP.h as and define which persist variables the data will be placed:

```
// Persist Variable used with CSS Constant Surface speed for Spindle
// These parameters will be set when GCode switches to G97 CSS mode
// A User program in KFLOP must be running to monitor the mode an x position
// and alter the spindle RPM appropriately.
#define PC_COMM_CSS_MODE 110 // Mode 1=Normal RPM mode. 2=CSS
#define PC_COMM_CSS_X_OFFSET 111 // X axis counts for Radius zero
#define PC_COMM_CSS_X_FACTOR 112 // X axis factor to convert counts to inches
#define PC_COMM_CSS_S 113 // S speed setting in inches/sec
#define PC_COMM_CSS_MAX_RPM 114 // Limit max RPM to this value as Radius approaches
zero
```

MODE: defines whether CSS is active or not. G96 sets all CSS parameters and then switches the mode to 2. G97 (normal fixed RPM Mode) sets the Mode to 1. On Power up the Mode will be 0. X\_OFFSET allows KFLOP to relate a position in counts to a radius from the spindle axis. It consists of all GCode Offsets converted to X axis counts. X\_FACTOR is the inverse of the X axis resolution which allows KFLOP to do a simple multiplication to convert X axis counts to inches. S: is the desired surface speed in inches/sec (converted from GCode units of feet/min or meters/min). MAX\_RPM: specifies the maximum allowed RPM. As the radius approaches zero the required RPM to maintain a specified surface speed will approach infinity. Any computed RPM beyond this value will be limited to this value. The max RPM may be specified on the line of GCode with the D word. If no D word is specified on the same line as the G96 then the limit will be sent as 1e9 RPM.

In most cases the supplied function ServiceCSS() shown below can be used. See C Program comments below on how to include this file into your Initialization C file and add a call to it in a continuous loop. If you already have a continuous loop in your Initialization C File then add a call ServiceCSS() within it. If there is not already an loop add one as shown in the comments below.

```
// Handle CSS (Constant Surface Speed) messages from KMotionCNC)
//
// This code assumes you have an Axis Channel Configured to control
// Spindle speed and Jog Calls can be made to control speed
//
// Include this function into your main Init Thread code and call it
// continuously from a forever loop similar to that shown here

#ifndef _SERVICECSS_H_
#define _SERVICECSS_H_

                Jog(SPINDLEAXIS,rpm * FACTOR * persist.userData[STATEVAR]);
            else
                Jog(SPINDLEAXIS,rpm * FACTOR);
        }
//      printf("xoff=%f radius= %f xfactor=%f s=%f(ips) maxrpm=%f
rpm=%f\n",*css_xoff, radius, *css_xfactor, *css_s, *css_max_rpm, rpm);
    }
}

```

## Step-by-step Recap

This sequence is applicable for Spindles that can be driven with a KFLOP Axis Channel:

#1 - Electrically Interface your spindle

#2 - Using KMotion.exe configure your Spindle Axis Channel and test that KMotion Console Screen Jog commands can successfully control it.

#3 - Modify MySpindleDefs.h with settings that apply for your system

#4 - Configure KMotionCNC | Tool Setup | M3 - M9 | M3, M4, M5, and S

#5 - If Spindle encoder feedback is available configure KMotionCNC | Tool Setup | Trajectory Planner | Threading

#6 - if CSS is desired include and add ServiceCSS() to a continuous loop in your Initialization C File

## Configuring an Axis to Control a DAC open Loop

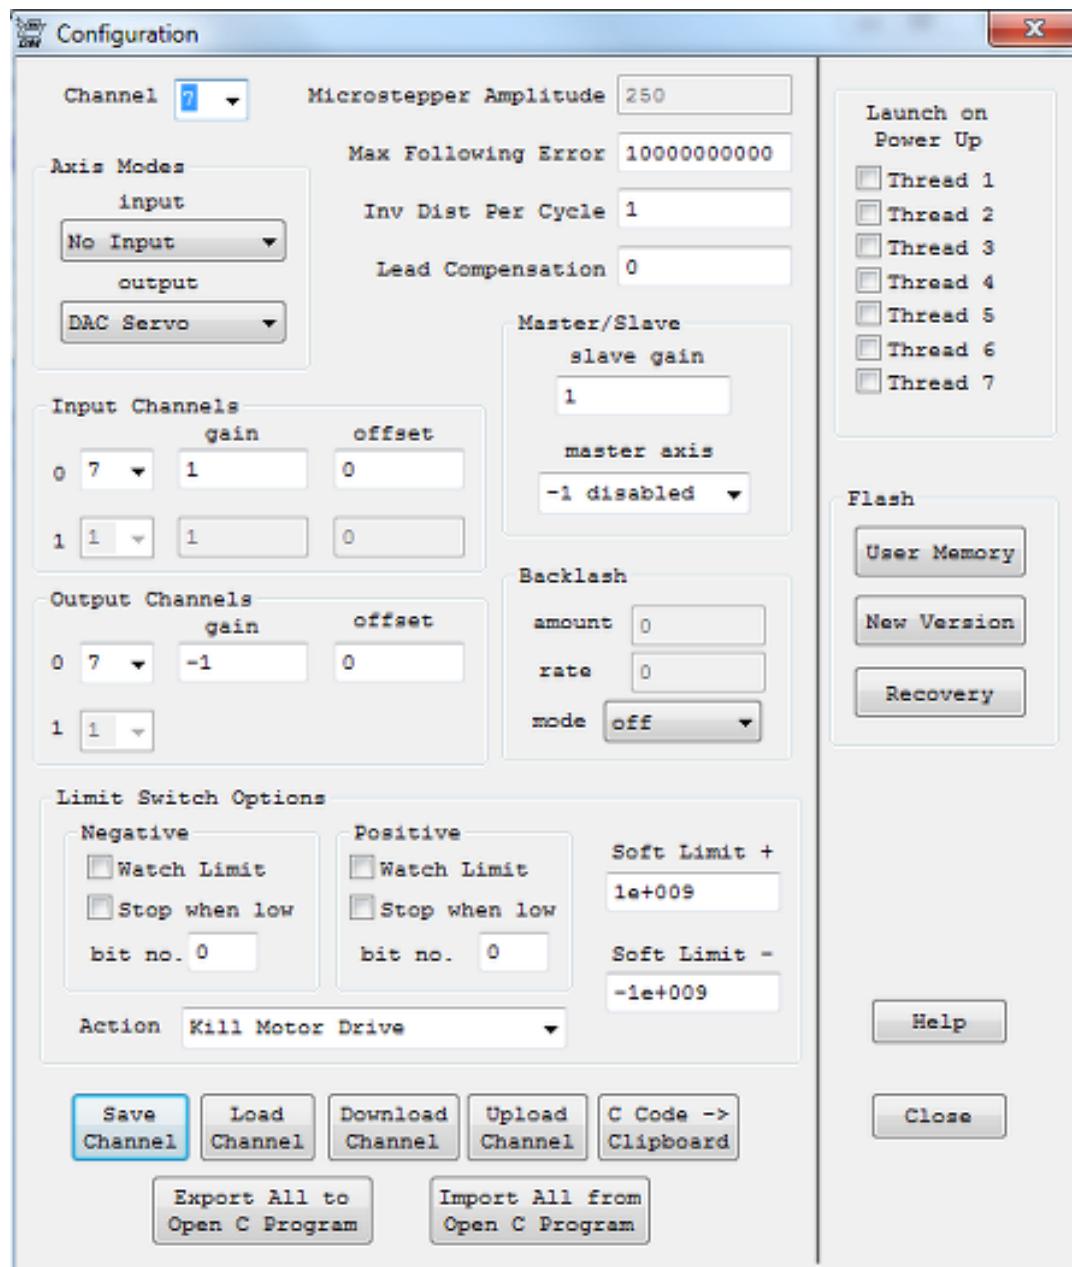

For Spindles that are controlled open loop with a 0-10V signal it is possible to configure an Axis Channel to output current Speed directly to a DAC. There are several advantages to configuring in this manner. First, the Spindle can be controlled using Jog Speed Commands in exactly the same manner as a closed loop servo (or any other) type of Axis Channel. And second the Axis Motion Profile Parameters (Acceleration and Jerk) can be used to ramp the speed up and down.

The configuration is the same as a DAC Servo with no Feedback (PID all zero) and with Velocity Feed Forward. The Servo diagram shows how the Motion Profile can be routed directly to the output using the Velocity Feedforward path:

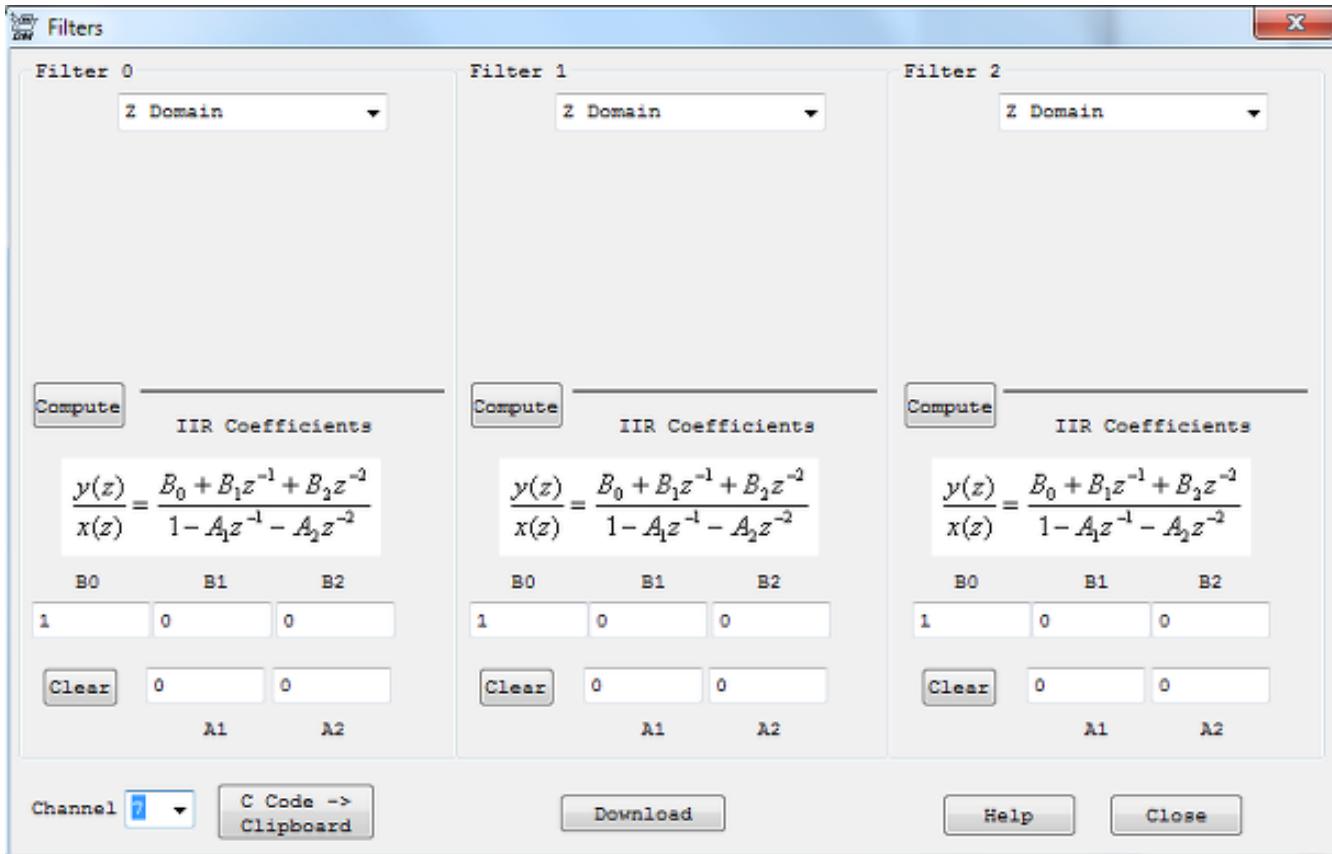

The Screens below show such a configuration. This configuration can be loaded from *AxisAsDAC7.mot*

No Input, DAC Output, Negative Gain, Infinite Following error:

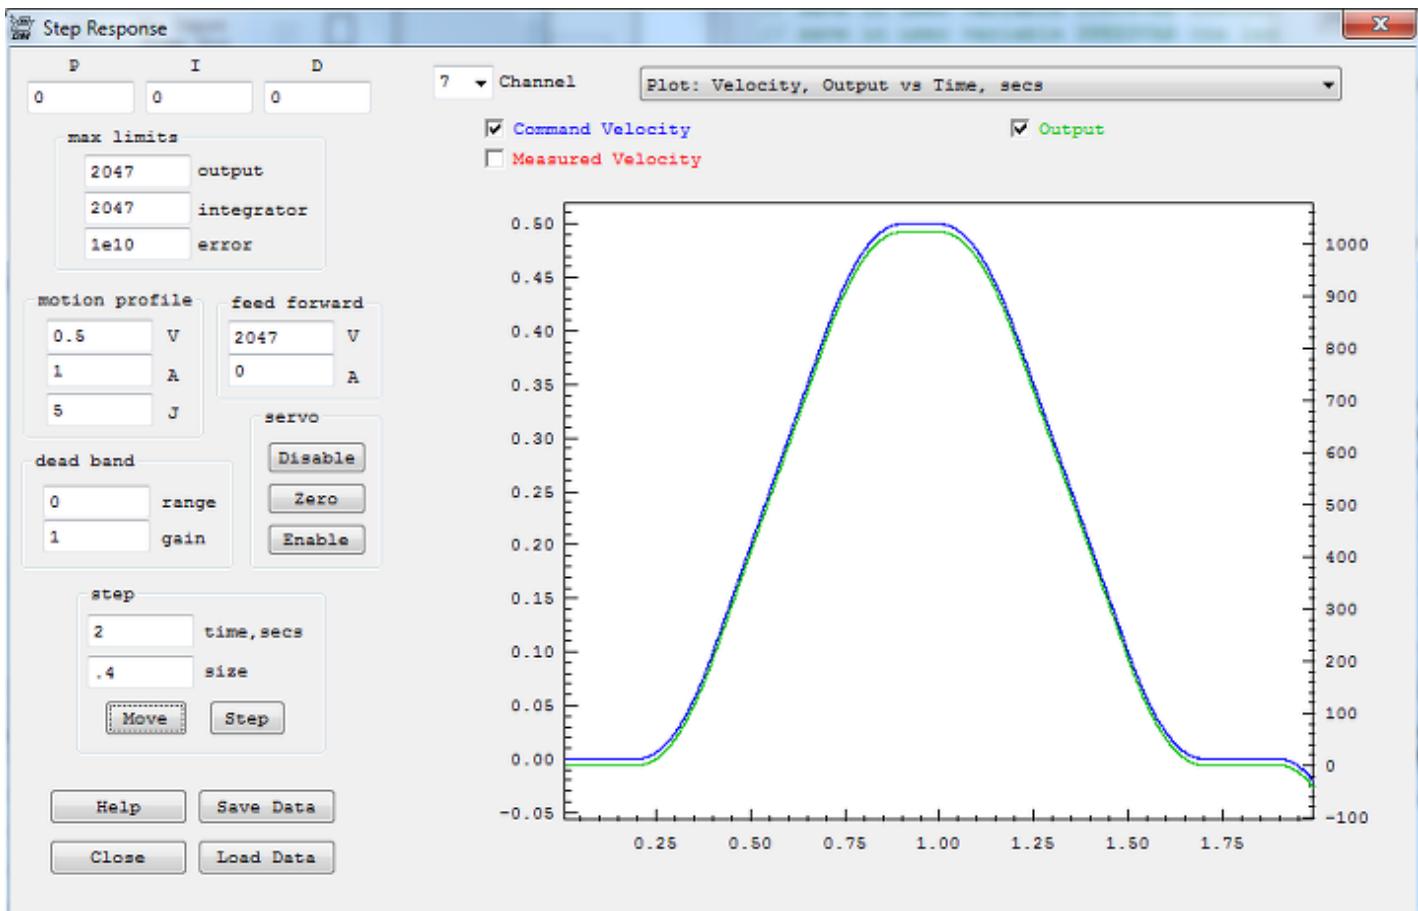

Filters all cleared to have Flat DC Gain=1

PID Zero, Max Output = full DAC Range of 2047 counts, Max Error Infinity, Feed Forward 2047 so that a velocity of 1 count/sec will generate full dac output.

Acceleration = 1 count/s<sup>2</sup> so that full speed will ramp up in 1 second, Jerk=5 counts/s<sup>3</sup> (Acceleration is "smoothed" over 1/5th second). This demonstration Move profile moves at 0.5 counts/sec which results in half of the full DAC output range (1023 counts or 5V analog). Note the output (green plot) follows the Commanded Velocity (blue) in perfect proportion. Any Velocity Range could be used because this is only a theoretical velocity profile and can be scaled to any proportion by the Velocity FeedForward. 1.0 counts/s is used to keep the math simple and to allow Jogging continuously for years without exceeding the Max error or Max Following Error limits.

You may also test your Spindle Axis using Console Screen Jog commands. For example Jog7=0.25 should drive the spindle at 25% full speed.

If your Spindle can accept a +/-10V signal to drive both directions then Jog7 = -0.25 should drive in the negative direction.

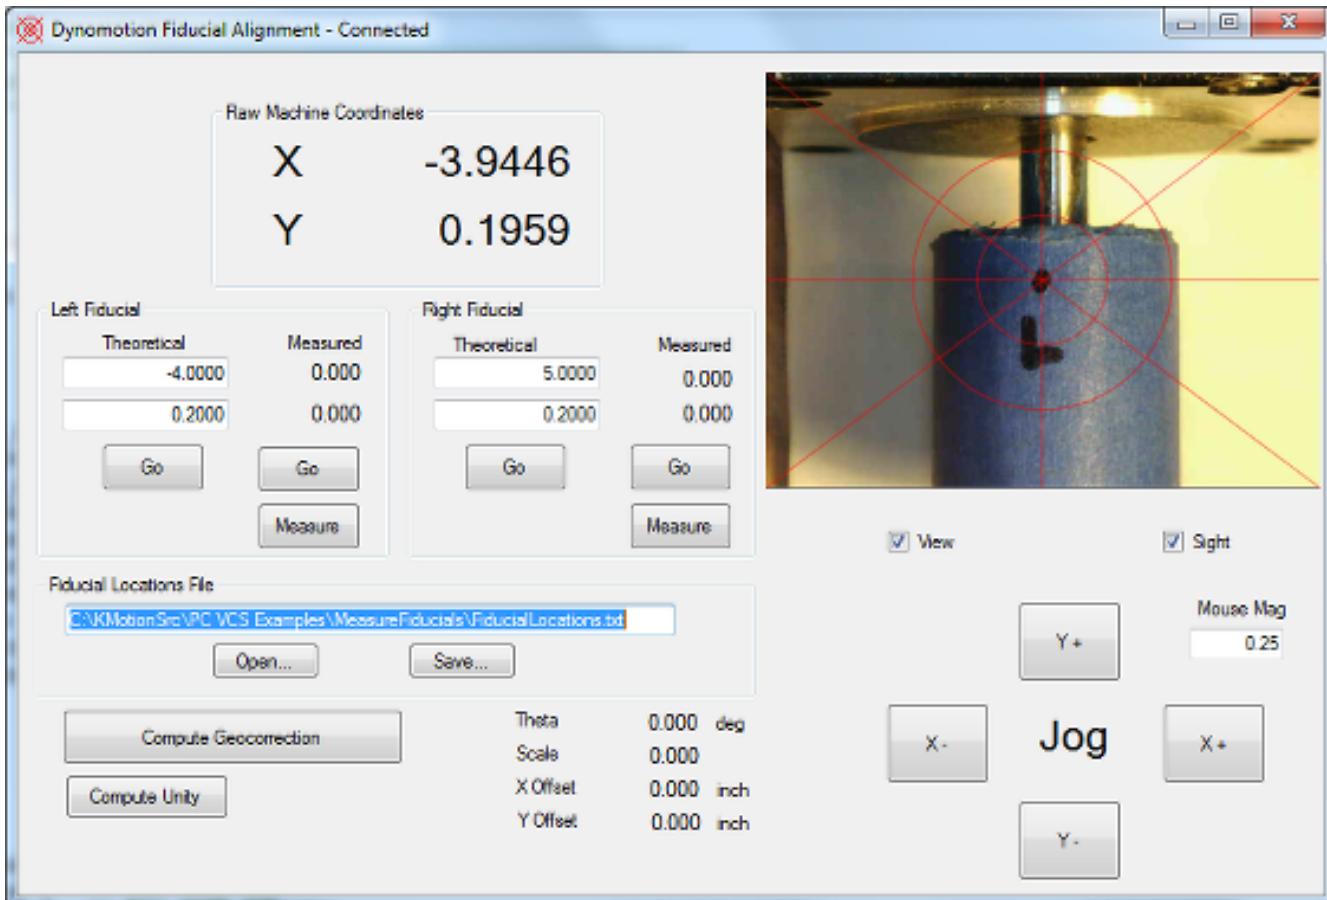

The standard SpindleUsingJogs examples can now be used for an open loop DAC controlled Spindle.

To determine the proper FACTOR in the MySpindleDefs.h file you will need to know what RPM your Spindle runs at when the full 10V analog signal is applied. This will correspond to the RPM where a full Jog Speed of 1.0 will be required. So for example if your RPM reading at 10V is 2500 RPM then configure:

```
#define FACTOR (1.0/2500.0) // to convert RPM to counts/sec
```

## KMotionCNC Fiducial Alignment

Fiducial Alignment using the external example C# program <Install>\PC VCS Example\MeasureFiducials

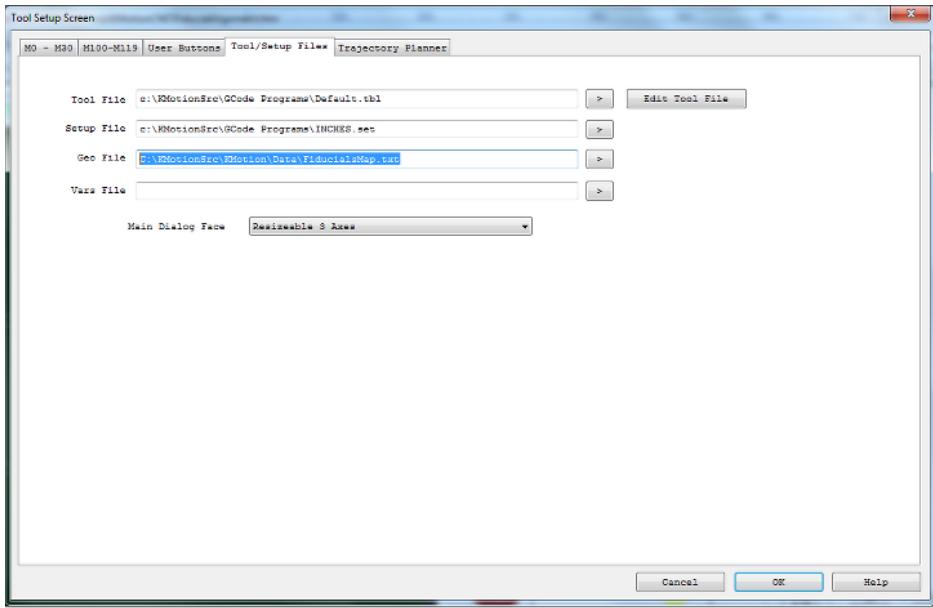

See Video: [https://youtu.be/a\\_p38zktlZI](https://youtu.be/a_p38zktlZI)

Measure Fiducials creates and overwrites the [Geometric Correction](#) file named:

<Install Directory>\KMotion\Data\FiducialsMap.txt

This should be configured for KMotionCNC to use in the [KMotionCNC | Tool Setup | Tool Setup Files configuration page](#) as shown here:

The created Geometric Correction File of 2x2 grid points in the form shown below. The table maps the corrected locations of a simple 1x1 inch square centered on the origin. Note that because the the Geo Correction Transformation extends outside the Grid using the closest Grid's Transformation the size and location of the square is not important.

```

2,2
1,1
-0.5,-0.5
0,0,-0.411272,-0.508541,0
0,1,0.598128,-0.507930,0
1,0,-0.411883,0.500859,0
1,1,0.597517,0.501470,0

```

The Measure Fiducials App loads Settings from a file named :

**<Install>\PC VCS Examples\MeasureFiducials\MeasureFiducialSettings.txt**

Which has this fixed format (avoid extra spaces or tabs). JogSpeed controls the Jog button speeds in counts/inch for both x and y. Resolution should be set to the same value as in KMotionCNC in counts/inch. If your system has more than one Video Capture Device you can control which is selected with the VideoDevice parameter. Zero would be the first detected. MouseMag adjusts the scale factor between Mouse movement and Axes movement.

**JogSpeed 600**  
**Resolution 10000 10000**  
**VideoDevice 0**  
**MouseMag 0.25**

KMotionCNC accepts a Window Event to Re-load the current Geometric Correction File. The C# Measure Fiducials Example finds any open KMotionCNC Window with:

```
[DllImport("User32.dll", SetLastError = true)]
public static extern IntPtr FindWindow(String lpClassName, String
lpWindowName);

IntPtr KMotionCNCWindow = FindWindow("KMotionCNC", null);
```

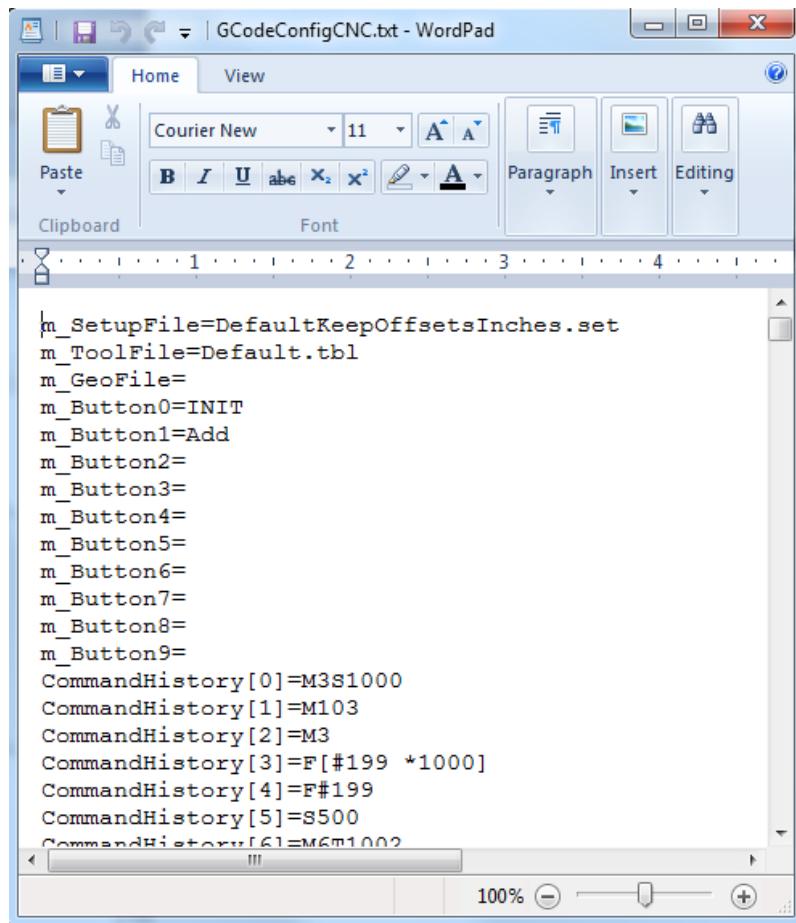

and sends the Window Event to KMotionCNC with:

```
[return: MarshalAs(UnmanagedType.Bool)]
[DllImport("user32.dll", SetLastError = true)]
public static extern bool PostMessage(IntPtr hWnd, uint Msg, int wParam,
int lParam);

uint WM_COMMAND = 0x0111;
int ID_ReloadGeoCorrection = 33016;
PostMessage(KMotionCNCWindow, WM_COMMAND, ID_ReloadGeoCorrection, 0);
```

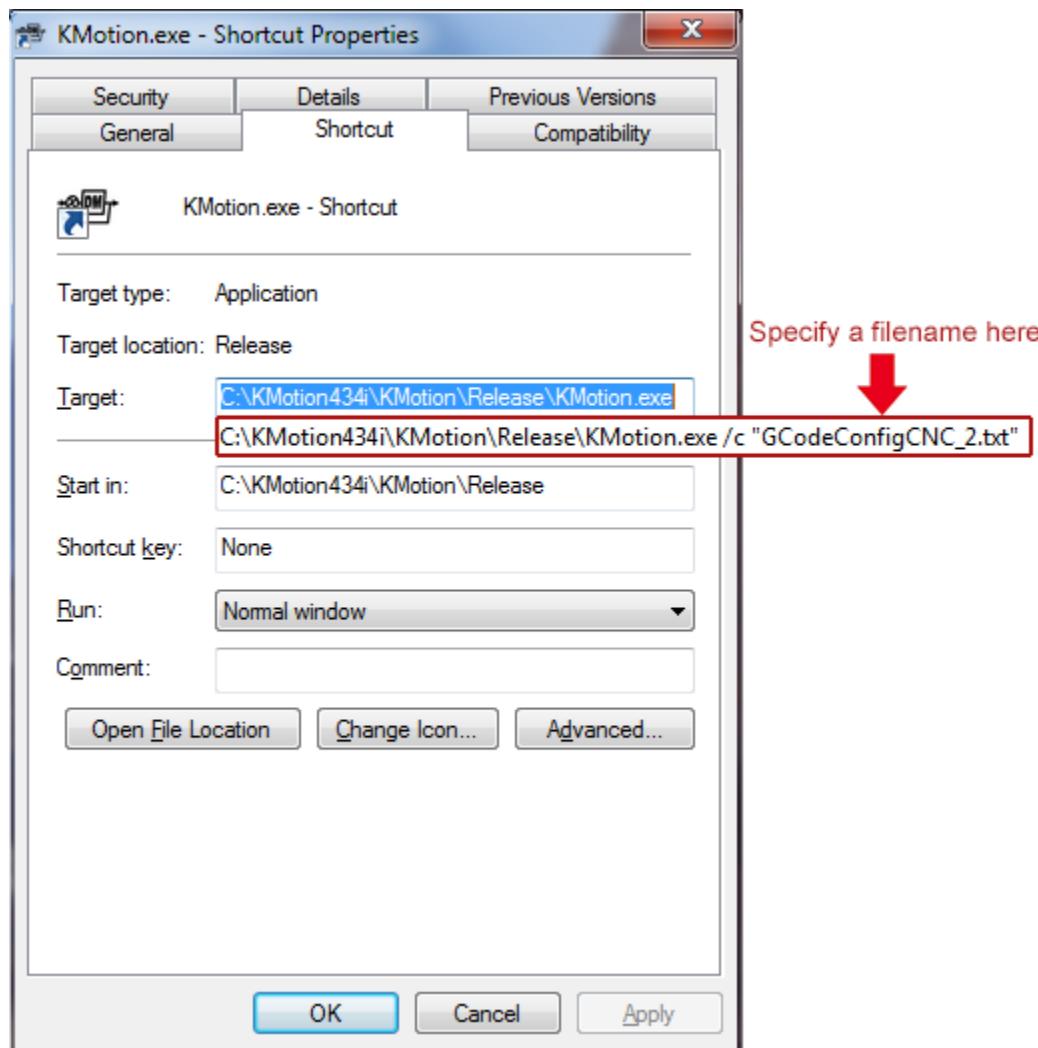

## Using Multiple Configurations

Users have the option of saving multiple configurations of KMotionCNC. The entire configuration of KMotionCNC (including all the tool setup files etc.) is stored in a single text file, by default called “**GCodeConfigCNC.txt**”, which is located in the **\KMotion\Data** directory. You can create multiple configurations and save them under different file names. See the configuration file opened in WordPad below:

```
m_SetupFile=DefaultKeepOffsetsInches.set
m_ToolFile=Default.tbl
m_GeoFile=
m_Button0=INIT
m_Button1=Add
m_Button2=
m_Button3=
m_Button4=
m_Button5=
m_Button6=
m_Button7=
m_Button8=
m_Button9=
CommandHistory[0]=M3S1000
CommandHistory[1]=M103
CommandHistory[2]=M3
CommandHistory[3]=F[#199 *1000]
CommandHistory[4]=F#199
CommandHistory[5]=S500
CommandHistory[6]=M6M100?
```

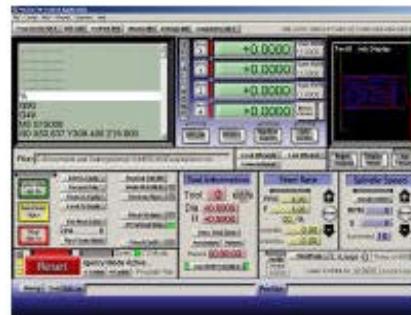

It is possible to create a Desktop icon to launch KMotionCNC using an alternate configuration file. First, create a shortcut to the new configuration by going to the \KMotion\Release directory and right-mouse-clicking on “**KMotion.exe**”, and select “Send to” and then “**Desktop (create shortcut)**”. Once the shortcut has been created, right-mouse click on it, select “**Properties**” and add the configuration file by adding /c “Filename” where “Filename” is the name of the configuration file to be used. Quotes are required if the filename contains spaces. Specify a filename which will be in the <Install>\KMotion\Data directory.

# Mach3 Plugin

+

## KMotion/KFlop Mach3

Mach3 is a popular CNC program available for purchase through [ArtSoftControls](#).

Traditionally Mach3 has relied on little hardware support and performed low level motion and even stepper motor step pulses directly by the PC. The pulses were output using the PC's parallel port. This required a special Microsoft Windows Kernel driver with a high interrupt rate and was limited to 50~100K steps per second.

Mach3 has the capability for adding "plugins" that allow additional functionality and hardware support. **DynoMotion** has developed a plugin that allows Mach3 to work with a **KMotion** or **KFLOP** Motion Controller. The offloads most of the real-time requirements from the PC, allows USB connectivity, much higher step rates, and allows easily adding other motor types including brushless servos.

This is an overview of the overall setup process of getting Mach3 and KMotion to play together.

1. Install Mach3
2. Install KMotion
3. Within KMotion configure/tune your motors
4. Within KMotion create a configuration and initialization program
5. Within Mach3 - configure plugin (enter name of KMotion Init program )
6. Within Mach3 - configure motor tuning (set resolution, speeds, and acceleration)
7. Within Mach3 - configure IO Bits.

Note: when using encoder feedback see also: [Mach3 Encoder Setup](#)

Note: for configuring probing see also: [Mach3 G31 Probe Setup](#)

Note: for information regarding operating steppers in closed loop see also: [Closed Loop Steppers](#)

Note: For passing Parameters see also: [Passing DROs](#)

Note: For Rigid Tapping see also: [Mach3 Rigid Tapping](#)

## 1. Install Mach3

Mach3 should be installed *before* KMotion so that the KMotion installation program can copy the necessary files (Dynomotion.dll) into the Mach3 plugin directory. The KMotion installation will also add a registry entry under "App Paths" so that Mach3.exe will have access to the necessary KMotion DLL libraries, programs, and data files

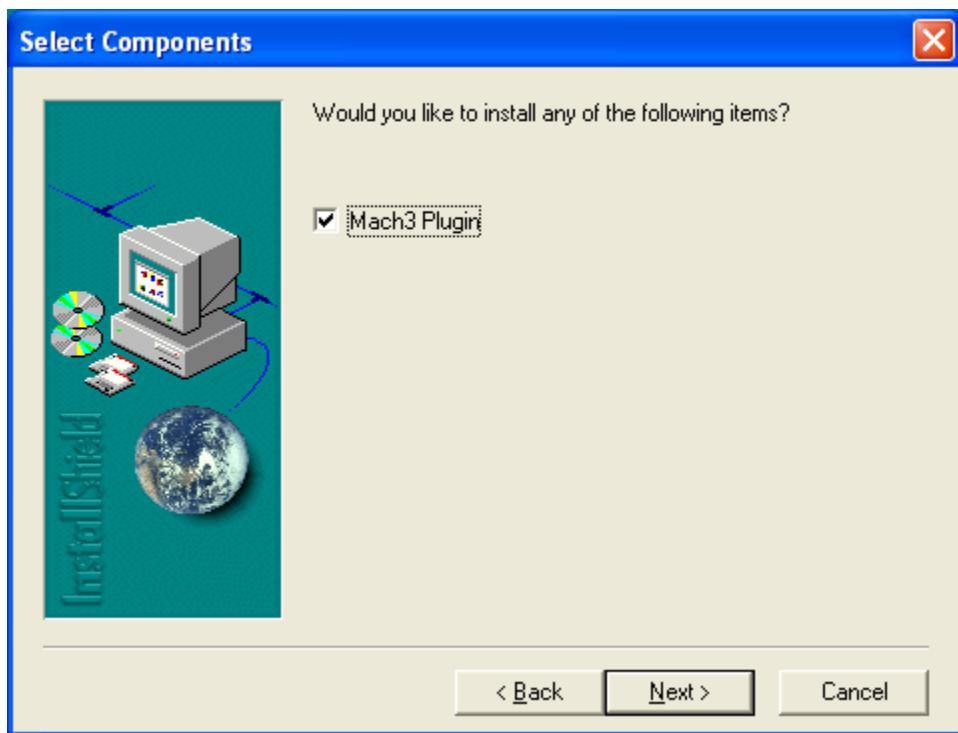

It is not necessary to load the Mach3 Kernel driver.

If KMotion has already been installed, it should be re-installed to make the necessary links between the programs.

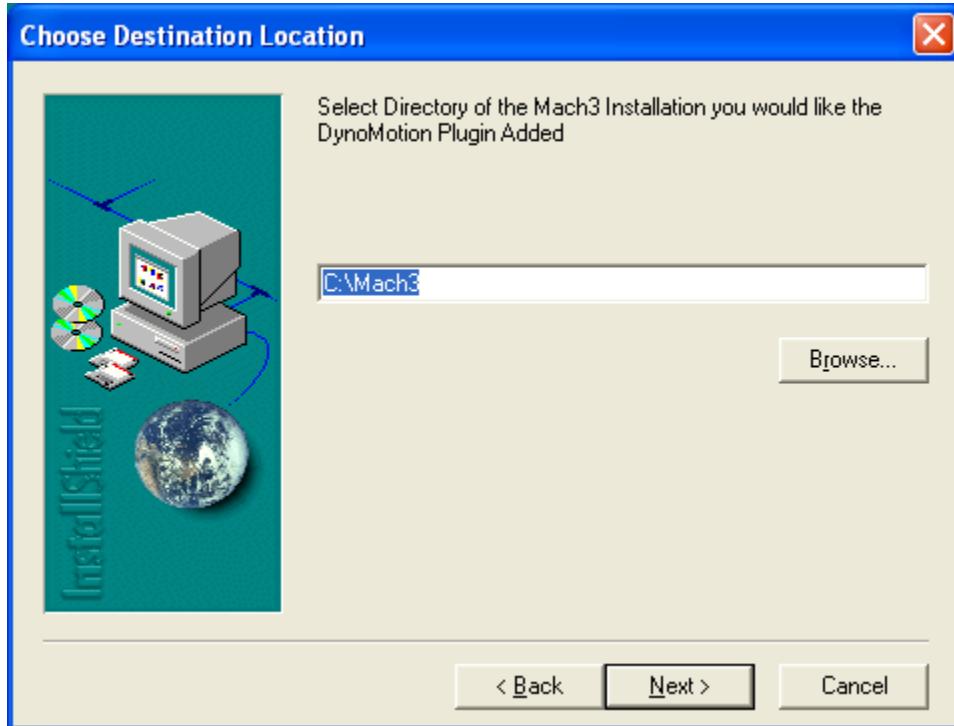

## 2. Install KMotion

At the end of the KMotion installation an option to install the Mach3 Plugin will be displayed.

Check the Mach3 Plugin option and select Next.

You will be prompted to enter the directory where Mach3 was installed.

A check will be made that a valid Mach3.exe exists in that directory, and the Dynomotion.dll will be copied to the plugins subdirectory.

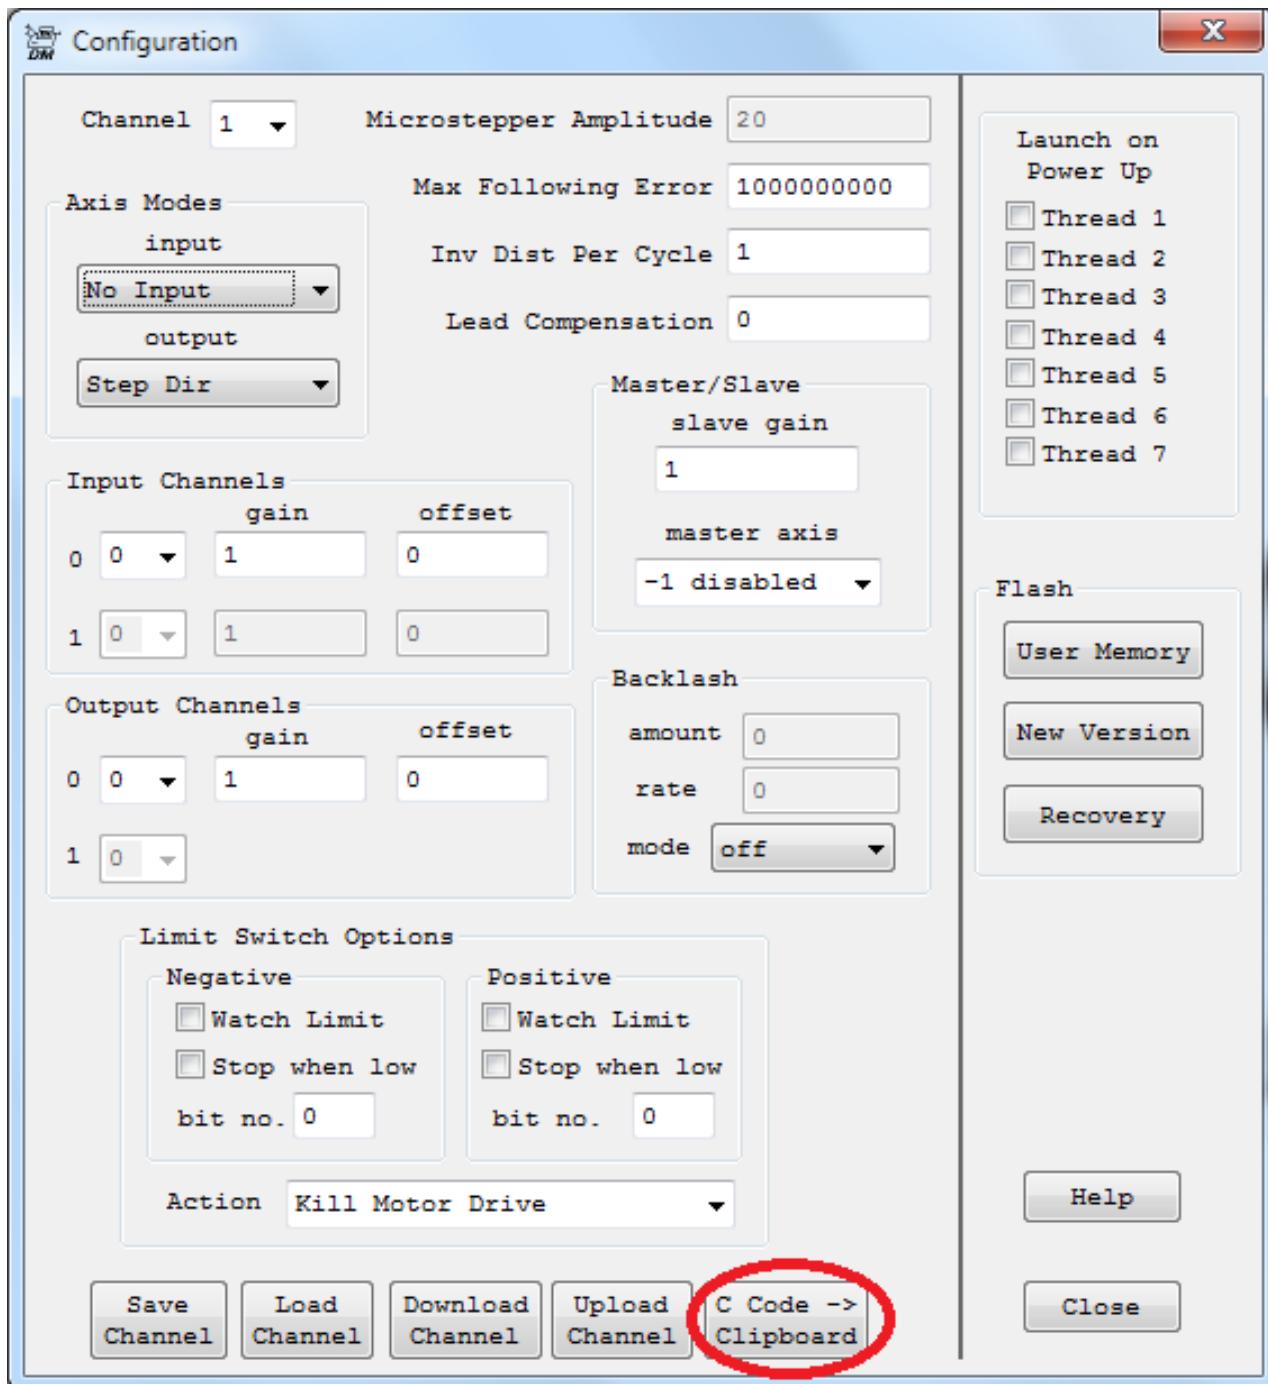

### **3. Within KMotion configure/tune your motors**

Follow the normal procedures to use the KMotion Executive program to configure and tune all of your motor axes. The simplest method to configure the system is to enter and change values in the various KMotion Executive Screens, download them to the KMotion Board, and test and tune for correct operation using the Step Response Screen as well as Console commands.

### **4. Within KMotion create a configuration and initialization program**

After each axis is functioning properly, the configuration for that axis can be copied to the clipboard as a valid C program code.

See the circled button below.

C Code to configure axis 0 might look like the code shown below. Detailed knowledge of C programming is not required to paste these into a User Program. The configuration for each axis should be pasted into a single program. Later this program may be executed at any time to completely configure the KMotion Board. The KMotion Executive program would not be needed to do this. The RESET button from within Mach3 will be configured to execute this program.

```
ch0->InputMode=ENCODER_MODE;
ch0->OutputMode=MICROSTEP_MODE;
ch0->Vel=100.00000;
```

```

ch0->Accel=1000.000000;
ch0->Jerk=10000.000000;
ch0->P=1.000000;
ch0->I=0.000000;
ch0->D=0.000000;
ch0->FFAccel=0.000000;
ch0->FFVel=0.000000;
ch0->MaxI=200.000000;
ch0->MaxErr=200.000000;
ch0->MaxOutput=200.000000;
ch0->DeadBandGain=1.000000;
ch0->DeadBandRange=0.000000;
ch0->InputChan0=0;
ch0->InputChan1=1;
ch0->OutputChan0=0;
ch0->OutputChan1=1;
ch0->LimitSwitchOptions=0x0;
ch0->InputGain0=1.000000;
ch0->InputGain1=1.000000;
ch0->InputOffset0=0.000000;
ch0->InputOffset1=0.000000;
ch0->invDistPerCycle=1.000000;
ch0->Lead=0.000000;
ch0->MaxFollowingError=1000000000.000000;
ch0->StepperAmplitude=250.000000;

ch0->iir[0].B0=1.000000;
ch0->iir[0].B1=0.000000;
ch0->iir[0].B2=0.000000;
ch0->iir[0].A1=0.000000;
ch0->iir[0].A2=0.000000;

ch0->iir[1].B0=1.000000;
ch0->iir[1].B1=0.000000;
ch0->iir[1].B2=0.000000;
ch0->iir[1].A1=0.000000;
ch0->iir[1].A2=0.000000;

ch0->iir[2].B0=1.000000;
ch0->iir[2].B1=0.000000;
ch0->iir[2].B2=0.000000;
ch0->iir[2].A1=0.000000;
ch0->iir[2].A2=0.000000;

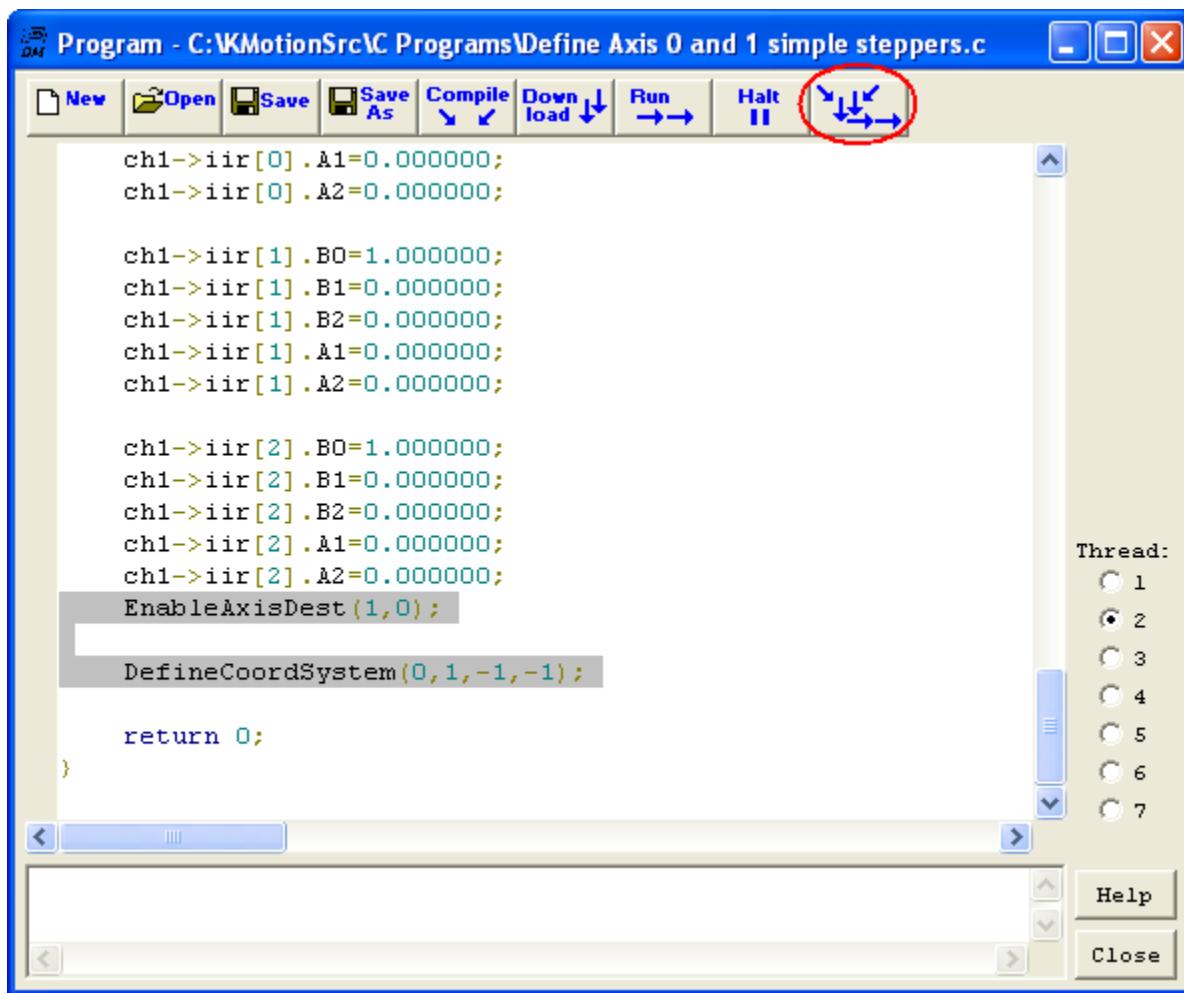

```

Besides C code to configure each axis, other commands such as those shown highlighted below may be used to enable each axis (and set the destination) and to define which axis channels are in the coordinated motion system. The DefineCoordSystem(0,1,-1,-1); statement defines a two axis

coordinate system where X is axis channel 0, Y is axis channel 1, and the Z and A axes are not used.

The circled button can be used to save, compile, download, and run the C program in one step. Note that once a C program has been executed to change configuration settings within the KMotion Board, the values in the KMotion Executive screens may be different from the current settings within the board. To synchronize the screens with what is actually in the board the channel should be "Uploaded".

Additional initialization operations may also be added to the C Program. These might include brushless motor phase finding, homing, activating IO bits, etc..

```

Program - C:\KMotionSrc\c Programs\Define Axis 0 and 1 simple steppers.c

Help Close

After the Initialization program is finalized and working it should be saved in a known location so that Mach3 may be configured to execute it as described in the next step.

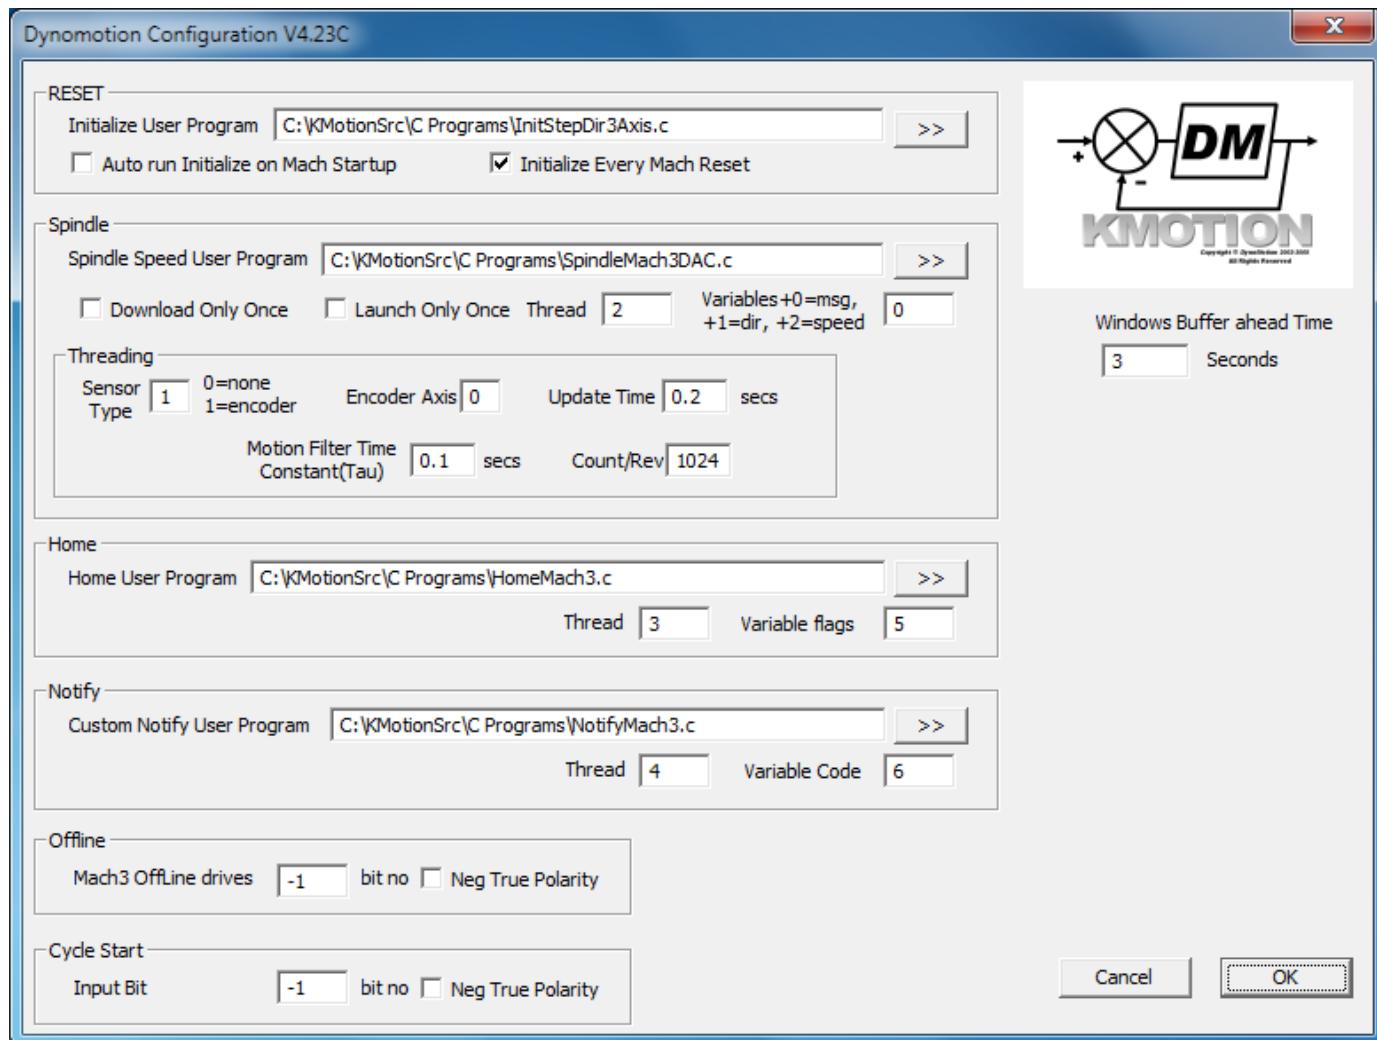

## 5. Within Mach3 - configure plugin (enter name of KMotion Init program)

We are now ready to Execute Mach3. The first time Mach3 is executed after adding the Dynomotion Plugin Mach3 will prompt the user which Motion Device should be used. The Dynomotion Plugin

should be selected. After the Mach3 Application comes up use the Config|Config Plugins menu to bring up the Config Plugins dialog shown below.

Next click in the circled area to bring up the Dynomotion Plugin Configuration Screen.

Specify the *KMotion Initialize User Program* that was created in step 4 above (you may browse to the file using the >> button).

Options to automatically run the program on Mach3 Startup or only once after Mach3 Startup may also be selected.

Mach3 generates Spindle Messages for On, Off, and Speed Changes. Specify a KMotion Spindle Speed User Program to handle and perform appropriate actions for the various Mach3 Spindle Messages. A default **SpindleMach3.c** program is included in the default installation that will simply print the messages and desired speeds requested by Mach3. Note that speed is a relative fraction of the max currently selected pulley's speed. Because KFlop/KMotion is likely to be controlling the motor speed regardless of the selected pulley, this is usually more appropriate. An appropriate User Program to perform the appropriate actions to actually drive the spindle should be created to replace the default program that simply prints the requested operation. There are included examples for Spindles controlled by a DAC output (SpindleMach3DAC.c) and for Spindles controlled by Step/Dir outputs (SpindleMach3Jog.c).

Spindle Speed measurement and Single point threading is also supported. A quadrature encoder is required on the spindle. Specify the Sensor Type as 1 to enable the Spindle measurement. Configure the Axis Channel that is configured to read the encoder (Note this is not the encoder channel, rather it is the axis that has the encoder channel configured as its input). Specify the Update time, Tau, and counts/rev. See [here](#) for more information.

Mach3 Home requests may be passed to a User Program to activate any desired Home Sequence. An example skeleton program which just prints the Mach3 home requests is included as **HomeMach3.c**. Another example for use with encoders is described [here](#).

Mach3 permits a general purpose mechanism to make custom calls to any Plugin that are passed through to a KFlop Custom Notify User Program. Placing a NotifyPlugins(10xxx) call in VB Script of either a Screen Button or Macro command may then trigger behavior in KMotion/KFlop. Message Codes from 10000 to 10999 will be sent to KFlop (all others are ignored). Plugin executions are automatically queued and executed in the sequence they were requested (the previous must complete before the next is launched). An example skeleton program which just prints the Mach3 notify requests is included as **NotifyMach3.c**. Another example for use with encoders is described [here](#).

An I/O bit may be defined that is activated when Mach3 goes into the offline state. Neg True Polarity may be checked if it is desirable for the bit to be driven low in the off-line state rather than high.

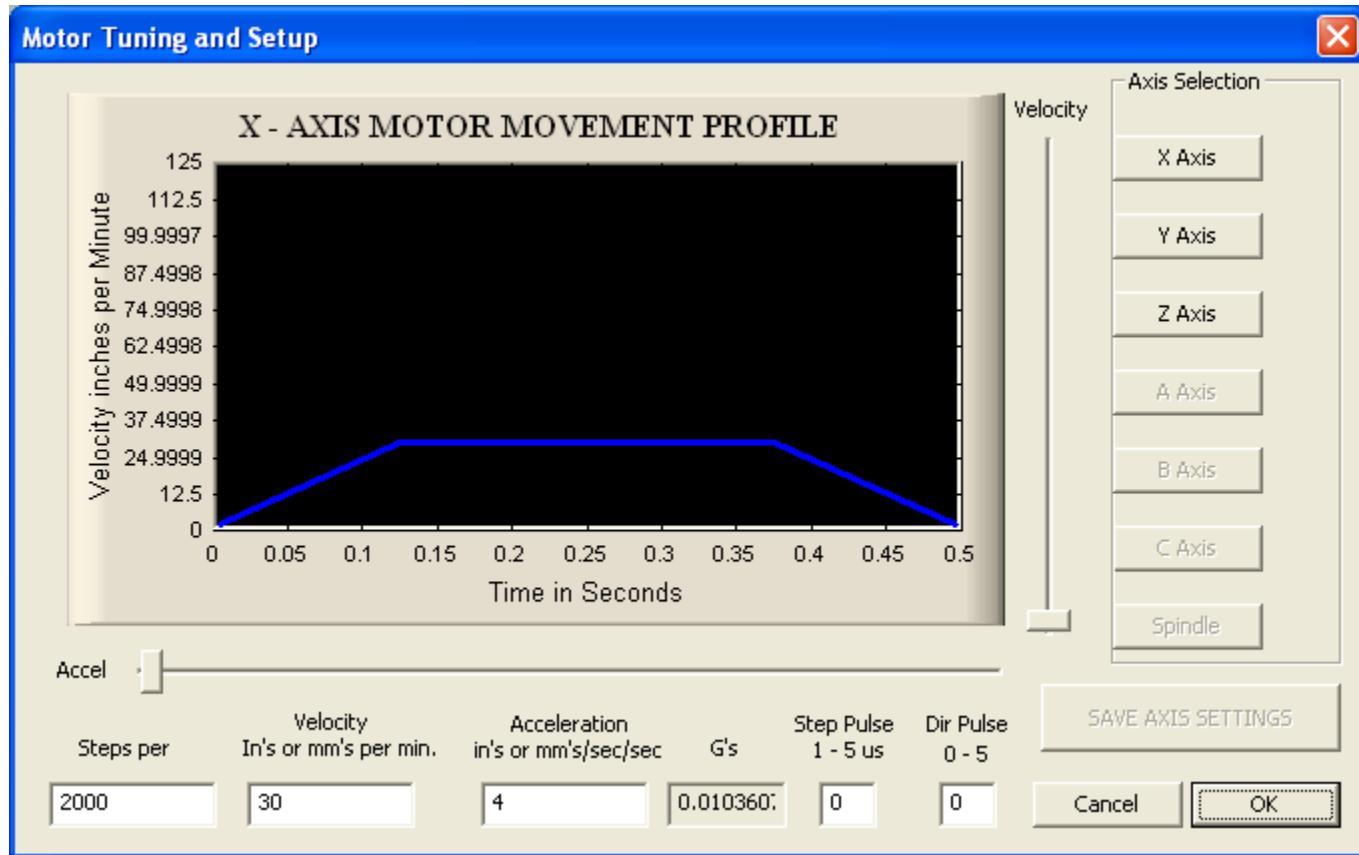

The *Windows Buffer ahead Time* may be changed to keep more or less buffering ahead in the KMotion Board. Using a value too small may cause the buffer to run empty and "starve" for data if Windows becomes non-responsive for longer than that amount of time. Using a value too large will cause feed rate changes and feed hold commands to be less responsive.

The plugin can be configured to *Automatically run Initialize on Mach Startup* if desired. **Caution:**This option should be left off if there is any potential danger with unexpected machine motion when launching Mach3.

After setting all parameters press OK to save the parameters into the Mach3 XML parameter file and return to the main Mach Screen. Pushing Mach3's Reset button will now execute the Initialize program.

## 6. Within Mach3 - configure motor tuning (set resolution, speeds, and acceleration)

Select **Config|Motor Tuning** to bring up the Motor Tuning Dialog. This screen allows the setting of Machine resolution, Max Velocity, and Max Acceleration for each axis in use. Note that the sliders are typically not very useful since the max step rates are much higher using a KMotion Motion Controller than with the original PC Generated Steps. It's usually best to just enter values directly into the cells.

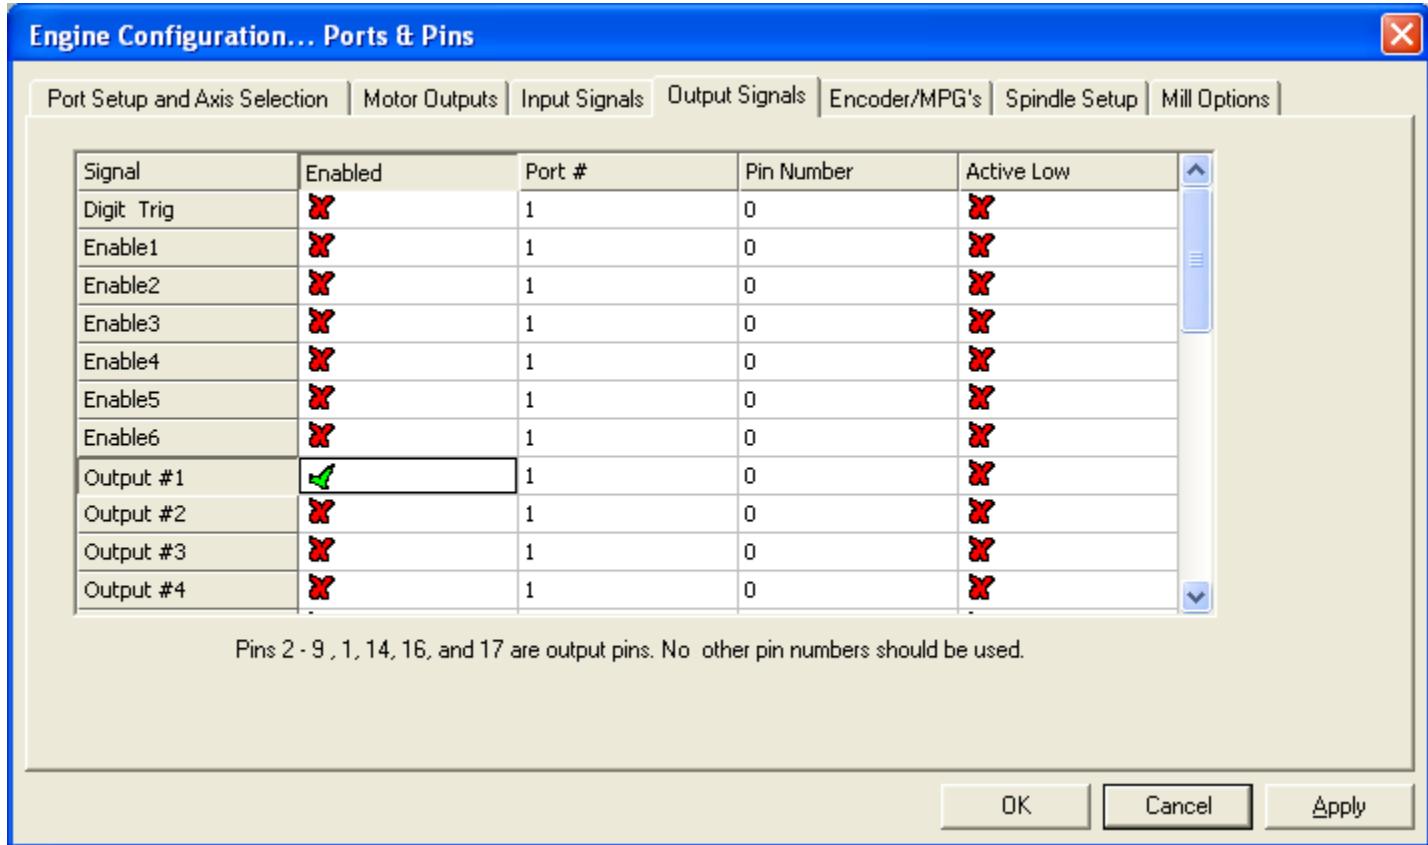

After the parameters have been entered and saved, Press OK to return to the main screen.

## 7. Within Mach3 - configure IO Bits.

Various M Codes may be used within Mach3 to activate IO bits on KMotion. Select the Menu **Config|Ports & Pins** to bring up the Dialog shown below. When using the KMotion Plugin, Pin Numbers now correspond to *KMotion IO Bit Numbers* rather than Parallel port Pins. Some of the terminology on the screen may be misleading as it was designed expecting to use a parallel port. For IO bit numbers less than 128 specify **Port#1**. For IO bit numbers 128 or larger, subtract 128 from the bit number and specify **Port #2** instead of Port #1. Extended Virtual IO bits 1024-1151 may also be accessed by specifying **Port #3** and subtracting 1024 from the bit number (note: the first 32 Virtual IO will consume less USB bandwidth because they are uploaded in the KFLOP Bulk Status record so use the first 32 if possible).

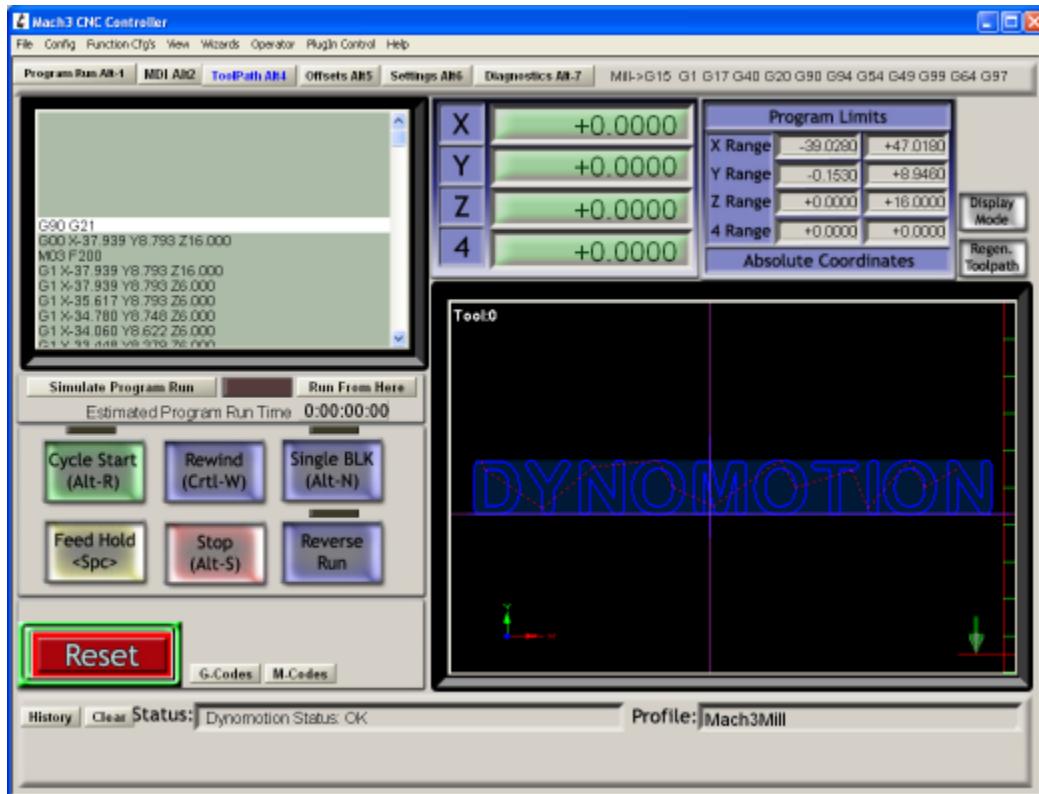

**Note:** Mach3 typically defaults after an initial install with Output #1 enabled for spindle control on Pin0 (as shown below). Bit 0 is often used on a KMotion board as an Encoder input. Having Mach configure the IO bit as an output will cause the encoder to be inoperable. Disable the output if this is the case.

That's it! Reset should now properly initialize the machine. Jogging and G Code should now be functional.

Refer to the Mach3 documentation for more information on advanced features.

Here is how a GCode file appears on Mach3 Mill.

Here the same example GCode file cut (or more accurately burned) into a piece of wood using a Harbor Freight Mini-mill driven with KMotion and Mach3.

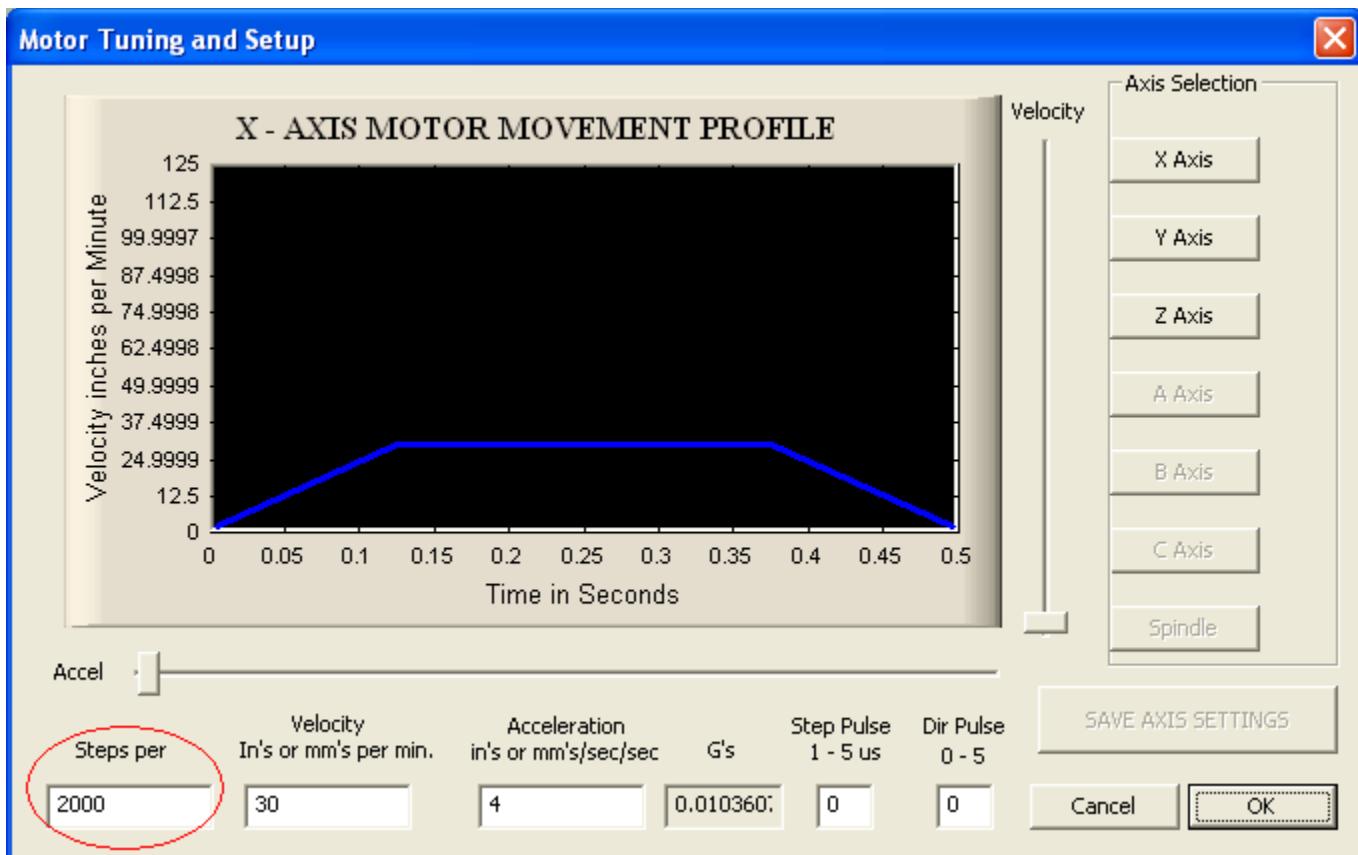

## Mach3 Plugin - with Encoders

The following describes the use of linear glass scale encoders or rotary shaft encoders with Mach3. The setup process described apply for KFlop operating in open loop mode with encoders as well as [closed loop control](#).

KFlop/KMotion should first be wired and configured such that the encoders are functional and scaled (using the InputGain0 parameter) so that the encoder counts match the commanded position in units of  $\mu$ steps. To verify that this is properly configured the KMotion.exe [Step Response Screen](#) may be used for verification. The Plot of Position Error should show small errors (typically <200  $\mu$ Steps) for a Move Plot if properly configured.

Since the encoder position is already scaled within KFlop/KMotion to match the  $\mu$ steps/Unit scale of the motor, the Mach3 Encoder resolution should be set to the same value as the Motor "Tuning" as shown below. The Encoder MPG screen is opened using the Config|Ports and Pins Menu. The Port and Pin definitions are not relevant when using KMotion/KFlop and should be set to some unused Port.

Engine Configuration... Ports & Pins

Signal	Enabled	A -Port #	A -Pin #	B -Port #	B -Pin #	Counts/Unit	Velocity
Encoder1	<input checked="" type="checkbox"/>	0	0	0	0	2000	100.000000
Encoder2	<input checked="" type="checkbox"/>	0	0	0	0	2000	100.000000
Encoder3	<input checked="" type="checkbox"/>	0	0	0	0	2000	100.000000
Encoder4	<input checked="" type="checkbox"/>	0	0	0	0	1.000000	100.000000
MPG #1	<input checked="" type="checkbox"/>	0	0	0	0	1.000000	100.000000
MPG #2	<input checked="" type="checkbox"/>	0	0	0	0	1.000000	100.000000
MPG #3	<input checked="" type="checkbox"/>	0	0	0	0	1.000000	100.000000

OK Cancel Apply

### Zero Buttons

Mach3 "Zeros" a DRO by adjusting the currently selected work offset such that the DRO will read zero. Since the glass scales are the best reference, the commanded position is adjusted to match the encoder position, before Mach3 is told to compute the new work offset.

'tell KFlop to set command to encoder  
'make sure mach updates  
'calculate work offset

In the **Config|Config Plugins|Dynomotion** set an appropriate KFlop User Program that will process the NotifyPlugin Message Codes to set KFlops internal Commanded Destination to the Current Encoder Positions. Typical program for 3 axes shown below. Note that the Message code is defined to be passed to the KFlop User Program via persist(userData[6])

***Example File: <Install Dir>\C Programs\NotifyZeroEncoderMach3.c***

```
#include "KMotionDef.h"

//Plugin calls for Mach3 NotifyPlugins Commands

#define X 0
#define Y 1
#define Z 2

main()
{
    int msg = persist(userData[6]; // Mach3 notify Message 10000-10999

    printf("Mach3 Notify Call, Message = %d\n",msg);

    if (msg==10100)
    {
        // adjust the commanded position to match the glass scale encoder
        DisableAxis(X);
        EnableAxisDest(X,chan[X].Position);
    }
    if (msg==10101)
    {
        // adjust the commanded position to match the glass scale encoder
        DisableAxis(Y);
        EnableAxisDest(Y,chan[Y].Position);
    }
    if (msg==10102)
    {
        // adjust the commanded position to match the glass scale encoder
        DisableAxis(Z);
        EnableAxisDest(Z,chan[Z].Position);
    }
}
```

***REF Buttons***

Mach3 REF buttons are used to set the initial Machine coordinates either by simply Zeroing them or performing a home operation into a switch.

The REF X, REF Y, REF Z etc... buttons may require editing using a screen editor. We recommend the one written by Klaus Dietz.

The Ref buttons should be edited to perform the standard Mach3 Ref operations. See the settings selected for the Ref buttons shown below when using Klaus' free Mach Screen Editor. The standard Ref operations for Mach3 is to request the Plugin to perform the Home Operation (actually labeled purge in the plugin).

The screenshot shows the configuration dialog for the 'X Ref' button. The title bar says 'Button'. The table below lists the settings:

Description	Value
Global	No
Function	Ref X
OEM-Code	1022
Hotkey	
Execute code	
Text on ctrl	X Ref
Locked for mouse	No

Button

Description	Value
Global	No
Function	Ref Y
OEM-Code	1023
Hotkey	
Execute code	
Text on ctrl	Y Ref
Locked for mouse	No

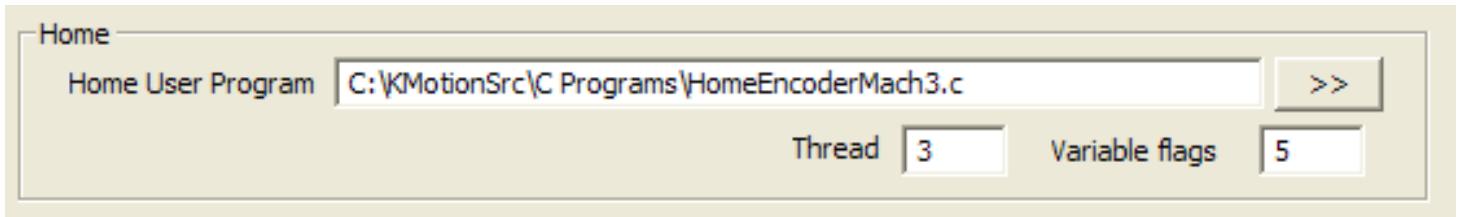

Button

Description	Value
Global	No
Function	Ref Z
OEM-Code	1024
Hotkey	
Execute code	
Text on ctrl	Z Ref
Locked for mouse	No

The Dynomotion Plugin passes these Home requests to KFlop to handle with a Home User Program. In the **Config|Config Plugins|Dynomotion** set an appropriate KFlop User Home Program. A **flag** variable is also passed to tell which axis is to be homed (Note that the flags is defined to be passed to the KFlop User Program via `persist(userData[5])`). In the case with encoders, both the Encoder Position and the Commanded Destination should be zeroed. Prior to Zeroing if any homing motion (to a switch for example - See: `SimpleHome3Axis.c` in the C Programs directory) may also be added into the program.

Note: if Homing Inputs are enabled in Mach3 | Config | Ports and Pins | Input Signals | X Home, Y Home, Z Home, A Home, B Home, C Home then Mach 3 will NOT call the Plugin to do Homing. Please make sure these Inputs are NOT enabled.

**Example File: <Install Dir>\C Programs\HomeEncoderMach3.c**

```
#include "KMotionDef.h"

//Plugin calls for Mach3 Home (actually Purge) Commands
//Called from Mach3 "REF" command
//in this case just Zero the measured position (encoder)
//and set the commanded destination to zero

#define X 0
#define Y 1
#define Z 2

main()
{
    int flags = persist(userData[5]; // Mach3 flags bit0=X, bit1=Y,
Bit2=Z, etc...

    printf("Mach3 Home Call, flags = %d\n",flags);

    if (flags & 1)
    {
        DisableAxis(X);
        Zero(X);
        EnableAxisDest(X,0.0);
    }
    if (flags & 2)
    {
        DisableAxis(Y);
        Zero(Y);
        EnableAxisDest(Y,0.0);
    }
    if (flags & 4)
    {
        DisableAxis(Z);
        Zero(Z);
        EnableAxisDest(Z,0.0);

    }
}
```

## Mach3 Plugin - Probe Setup

The following describes the use of DynoMotion Probing with Mach3. Probing in Mach3 is selected by using the G31 code. Such as:

### **G31 Z-4 F40**

This example command line would cause a motion from the current position to a absolute position of z = -4 at a feed rate of 40 units/minute and stop as soon as the probe input becomes active.

When the probe input becomes active the current positions of all axes will be captured and the motion will decelerate to a stop in a controlled manner. Mach3 variables 2000-2005 will be filled with the captured position.

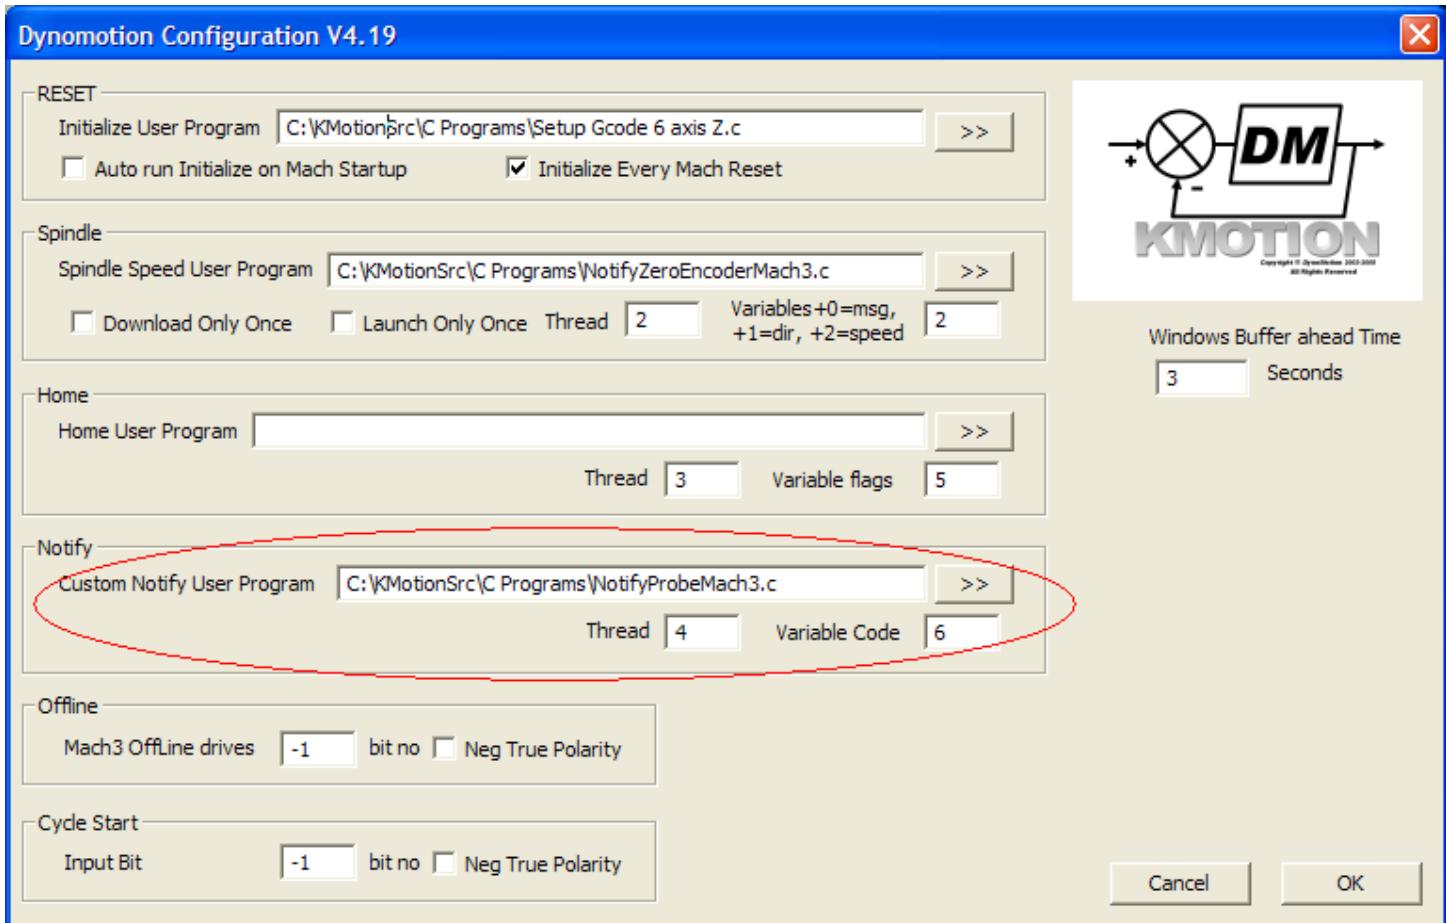

The following sequence might be used to perform a probe and then perform a move relative to the captured Z position.

**G31 Z-4.0 F40 (Probe in Z)  
G1 Z #2002 (move back to trip point)  
M30**

*Note: If the Probe input is already active at the beginning of the probe, or the motion completes without the Probe input ever becoming active, an error will be displayed and G Code execution will stop.*

### **Required KMotion/KFLOP User Program**

In order to perform Probing, the Notify User Program must be configured to properly handle message 20000 and selected in the Mach3 Plugin configuration.

Add the message handler shown below to the Notify program for your system. During probing the DynoMotion Plugin sends a Notification 20000 message to the configured KMotion/KFlop Notify User Program.

The message handler must:

```
#1 set status (user var 62) to zero
#2 wait for the probe to become active
#3 sample the current positions of the defined axes (as doubles into 50-61)
#4 set status to 1 or 2 depending on if the probe was ever inactive
#5 feedhold the system
#6 exit
```

**Note:** defines below in PC-DSP.h should be used to symbolically reference the persist(userData Variables

```
#define MACH3_PROBE_STATUS_VAR 62
#define MACH3_PROBE_RESULTS_VAR 50
```

In most cases the only modification required will be the defined bit number and active state.

However any number of other techniques might be used such as monitoring analog inputs, or capturing other variables such as encoder positions.

### ***Excerpt from Example File: <Install Dir>\C Programs\NotifyProbeMach3.c***

```
// handles probing
//
// flag is 0 - while watching for probe hit
// flag is 1 - if probe was already set from start
// flag is 2 - after successful probe hit
// flag is 3 - Tells Plugin to upload status (3) to
//               DRO 1100 and let User handle the error
//
// returns the captured results in User Variables
// X - 50+51
// Y - 52+53
// Z - 54+55
// A - 56+57
// B - 58+59
// C - 60+61
// status result 62

#define PROBE_BIT 0
#define PROBE_ACTIVE_STATE 1
#define PROBE_ERROR_HANDLING 0 // 0 Stops Mach3 on probe error
// #define PROBE_ERROR_HANDLING 3 // 3 User must query DRO 1100 and
handle error

if (msg==20000)
{
    double *d = (double
*)&persist(userData[MACH3_PROBE_RESULTS_VAR];
    int flag=1;

    persist.userData[MACH3_PROBE_STATUS_VAR]=PROBE_ERROR_HANDLING
;

    while (ReadBit(PROBE_BIT)!=PROBE_ACTIVE_STATE)
    {
        flag=2;
        WaitNextTimeSlice();
    }

    if (CS0_axis_x>=0) d[0]=chan[CS0_axis_x].Dest;
    if (CS0_axis_y>=0) d[1]=chan[CS0_axis_y].Dest;
}
```

```
if (CS0_axis_z>=0) d[2]=chan[CS0_axis_z].Dest;
if (CS0_axis_a>=0) d[3]=chan[CS0_axis_a].Dest;
if (CS0_axis_b>=0) d[4]=chan[CS0_axis_b].Dest;
if (CS0_axis_c>=0) d[5]=chan[CS0_axis_c].Dest;

persist(userData[MACH3_PROBE_STATUS_VAR]=flag;
StopCoordinatedMotion();
}
```

## **Mach3 Plugin - Passing DROs**

### **Mechanism for transferring values back and forth between Mach3 and KFLOP**

Mach3 User DROs 1 to 50 map to KFlop UserData 0 to 99 (2 words each double)

To Read from KFLOP to Mach3 use NotifyPlugins codes 18001 to 18050

To Write from Mach3 to KFLOP use NotifyPlugins codes 19001 to 19050

### **Example MACH3 SIDE**

```
SetOEMDRO(1007,123.456)      'Put a value in a Mach DRO
NotifyPlugins(19007)          'Send it to KFLOP
Sleep(3000)                  'Wait for KFLOP to modify and copy it
NotifyPlugins(18008)          'Read the result from KFLOP
x=GetOEMDRO(1008)            'Check the value passed back
```

### **Example KFLOP SIDE**

```
#include "KMotionDef.h"
#define DROIN 7
#define DROOUT 8

main()
{
    double *pin = (double *)&persist(userData[(DROIN -1)*2];
    double *pout = (double *)&persist.userData[(DROOUT-1)*2];
    for(;;)
    {
        Delay_sec(2);
        *pout = *pin + 999;
        printf("DROIN %d = %f DROOUT %d=%f\n",DROIN,*pin,DROOUT,*pout);
    }
}
```

## ***Mach3 Plugin - Rigid Tapping***

To perform Rigid Tapping from Mach3 the tapping parameters are set into GCode Variables, then a Macro (M84) is called which downloads the parameters to KFLOP, notifies KFlop to perform the Tap Cycle, then waits until KFLOP sets a variable indicating the operation has completed.

A requirement for Rigid Tapping is that the Spindle has encoder feedback and is possible to move in a fairly controlled manner. The Z axis motion is "geared" to the measured Spindle Encoder Position throughout the cycle.

There are three parts to the process: The GCode, the M84 Macro, and the KFlop User Program. Examples can be found [here](#).

### ***Example Rigid Tap Call From GCode***

We use a Macro M84 as Mach3 uses the normal G84 Tap cycle for a floating tapholder technique and doesn't currently support a rigid tap GCode.

Note that the forward cutting rate (RPM) and the retraction rate (RPM) can be defined separately. A cyclic forward/retract motion can be specified to cut the thread to the total depth. If a simple single motion is desired, set the Z depth forward motion to the Z depth Total.

G0X0Y0Z5

(Call a Rigid Tap Sequence)  
#10=20 (TPI - Threads per inch)  
#11=700 (Forward Cutting RPM)  
#12=1000 (Retract RPM)  
#13=0.75 (Z depth Total inches)  
#14=0.2 (Z depth Forward per Motion)  
#15=0.05 (Z depth Retract per Motion)  
M84

G0X4Y0Z5

(Call a Rigid Tap Sequence)  
#10=20 (TPI - Threads per inch)  
#11=700 (Forward Cutting RPM)  
#12=1000 (Retract RPM)  
#13=0.75 (Z depth Total inches)  
#14=0.2 (Z depth Forward per Motion)  
#15=0.05 (Z depth Retract per Motion)  
M84

M2

**Mach3 M84 Macro**

This macro moves the GCode Tapping Variables to Mach3 User DROs, downloads then to KFLOP UserData variables, Triggers KFLOP to perform the Tap Cycle, then waits until KFLOP sets a User Data Variable indicating the cycle is complete.

```
'Macro for Rigid Tappin with Dynomotion KFLOP
```

```
' pass variables to KFLOP
```

```
' Var DRO KFLOP UserVar Description
' #10 1010 18 19 TPI - Threads per inch
' #11 1011 20 21 Forward Cutting RPM
' #12 1012 22 23 Retract RPM
' #13 1013 24 25 Z depth Total inches
' #14 1014 26 27 Z depth Forward per Motion
' #15 1015 28 29 Z depth Retract per Motion
' 1016 30 31 Set by KFLOP when complete
```

```
'Move the GCode Vars into DROS and send them to KFLOP User Vars
```

```
For i=0 To 5
```

```
Call SetUserDRO(1010+i, GetVar(10+i))
```

```
NotifyPlugins(19010+i)
```

```
Next i
```

```
Call SetUserDRO(1016, 0) 'clear the complete flag
```

```
NotifyPlugins(19010+6)
```

```
NotifyPlugins(10084) 'do the TAP!!
```

```
While GetUserDRO(1016)=0
```

```
Sleep(50)
```

```
NotifyPlugins(18016) 'upload the complete flag
```

```
Wend
```

**KFLOP Notify User C Program that performs the Rigid Tap Cycle**

The C Program that performs the Rigid Tap Cycle. This assumes that the Spindle axis can be controlled like a Servo Axis within KFLOP (although it is not defined as an axis within Mach3). The defines must be set per your specific system. A low pass filter is used to smooth the commanded Z motion for the case where the Spindle Motion might be too Jerky for the Z Axis to follow without possibly stalling, it also smoothes the response that would be otherwise stepped because user programs only execute every other servo sample. A Tau of 0.001 performs as a low pass filter with a time constant of 1ms.

```

#include "KMotionDef.h"

## KStep - Connector Pinouts

## J1 Motor Power

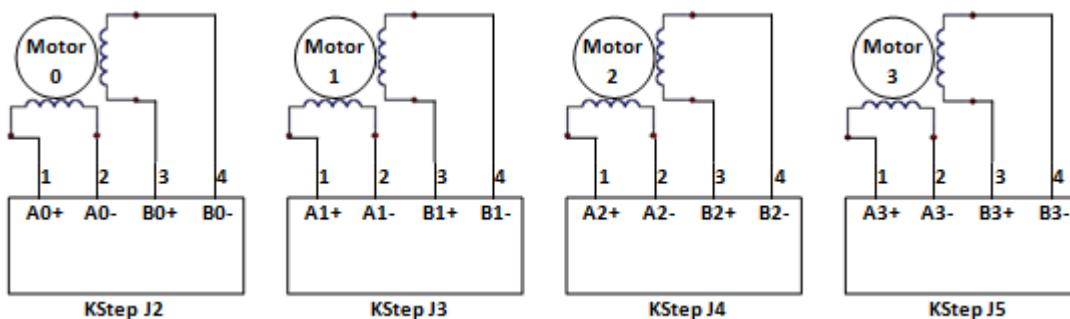

Motor power VBB from 12-48V may be applied through J1 or alternately through JR1. For applications that require more than 10A of supply current both of the GND and VBB connections should be used.

**Caution Voltage Clamp jumpers must be set to a Higher Voltage than the applied voltage.**

**Caution if JR1 is connected to a PC Power Supply 12V will be applied to VB**

## J2 J3 J4 J5

J2 Motor 0  
A+ A- B+ B-

J3 Motor 1  
A+ A- B+ B-

J4 Motor 2  
A+ A- B+ B-

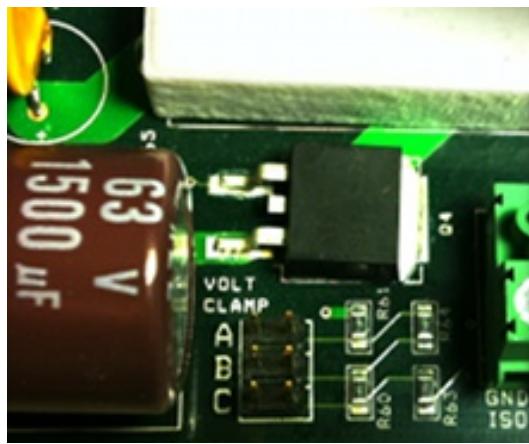

J5 Motor 3  
A+ A- B+ B-

Connect Stepper Motors to connectors J2 through J5. A Stepper Motor has two independent coils A and B. This should be verified with an Ohmmeter. Connect one motor coil across the A terminals and the other coil across the B terminals.

***Caution cross wiring the motor terminals is likely to cause damage to KStep and/or the motor.***

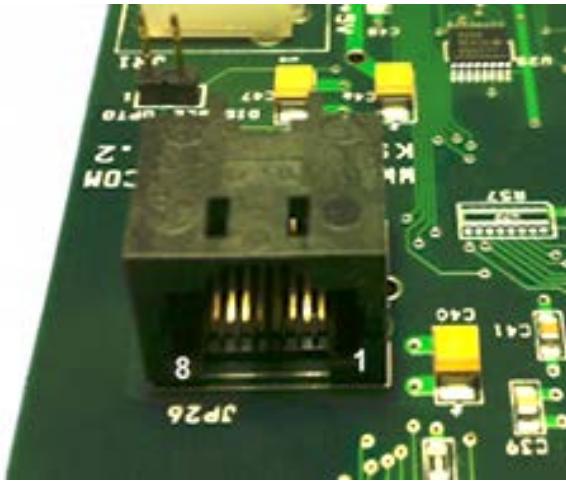

## Voltage Clamping

KStep features a jumper programmable Voltage Clamping Circuit. Voltage spikes due to Regenerative Braking and other sources can potentially raise the supply voltage up to a level that can damage electronics including KStep or the power supply. Voltage Spikes may also cause a power supply to trip a fault and shut down. KStep's Voltage clamp can be used to avoid these problems. KStep's Voltage Clamp can be programmed for 4 different voltage levels. It is not possible to disable the Voltage Clamp but the clamping voltage level may be changed. With all jumpers removed the Voltage will be clamped at 49V. Each jumper added will reduce the Clamping voltage by 12V. The order of the jumpers is not important as each reduces the Voltage by the same amount (12V). This allows common supply voltages of 12, 24, 36, and 48V to be used.

***Caution connecting a supply voltage higher than the clamping voltage will draw excessive current and is likely to cause damage to KStep or the Power Supply.***

Jumpers Installed	Example	Clamping Level
None	None	49V
1	A	37V
2	A+B	25V
3	A+B+C	13V

**JP26**

KStep can accept Step/Dir signals in from either JP26 or JP36 whichever is more convenient. Normally if two KSteps are connected to KFLOP in order to have 8 axes in the system then JP26 will be used for the 2nd KStep. KFLOP drives Step/Dir Generators 4 - 7 on its JP5 connector which when connected to KStep's JP26 connector will drive Motors 0 - 3. When driving signals into JP26 GND, +5V and Enable must be provided into KStep in some manner. J6 is usually the simplest but JR1 and JP36 are also possibilities.

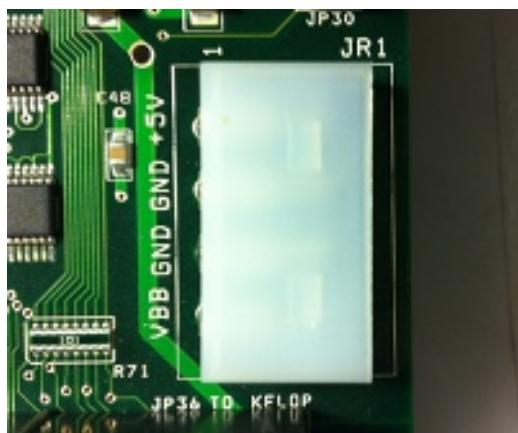

Pin	KFLOP Name	KFLOP Output	KStep Input
1	IO36	Step 4	Step 0
2	IO37	Dir 4	Dir 0
3	IO38	Step 5	Step 1
4	IO39	Dir 5	Dir 1
5	IO40	Step 6	Step 2
6	IO41	Dir 6	Dir 2
7	IO42	Step 7	Step 3
8	IO43	Dir 7	Dir 3

### ***Disable Optos Jumper***

KStep normally drives JP36 pins 11 - 14 with selected Opto Input Data. If Opto Input Data is not desired this jumper disables this feature and leaves these pins in a high impedance state. This might be necessary if the connection to KFLOP desires to use the associated pins for some other purpose such as KFLOP Encoder inputs #2 and #3.

### ***JR1***

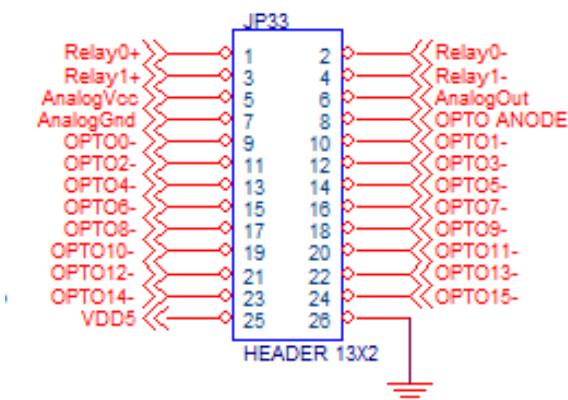

JR1 is a molex Disk drive type connector that can be used to provide Motor power (VBB) and +5V to KStep. Motor power is common to all 4 Motor Drives and may be applied either through JR1 or J1 screw terminals. A PC Power Supply often provides +5V on pin 4 and +12V on Pin 1 so caution should be made to assure different power supply voltages are not connected to both JR1 and J1. The +5V connection is used to power the Motor driver circuits. The +5V and GND connections are to the motor side of the isolation and will be isolated from the KFLOP side if the Isolation Jumpers are removed.

**JP33**

**JP33 IO**  
**Relay Drv Out**  
**Opto IN**  
**Analog Out**

KStep adds 2 opto isolated relay drivers (100ma @ 36V), one Analog Output, and 16 opto isolated 12-24V inputs. All these IO are optically isolated regardless of the Isolation Jumpers set for the Isolation on the Step/Dir and enable signals. Opto Inputs have a common Anode normally connected to either +12V or +24V. Shorting any of the OPTO- pins to GND will activate the input. The Opto Inputs have a 10K ohm series resistance.

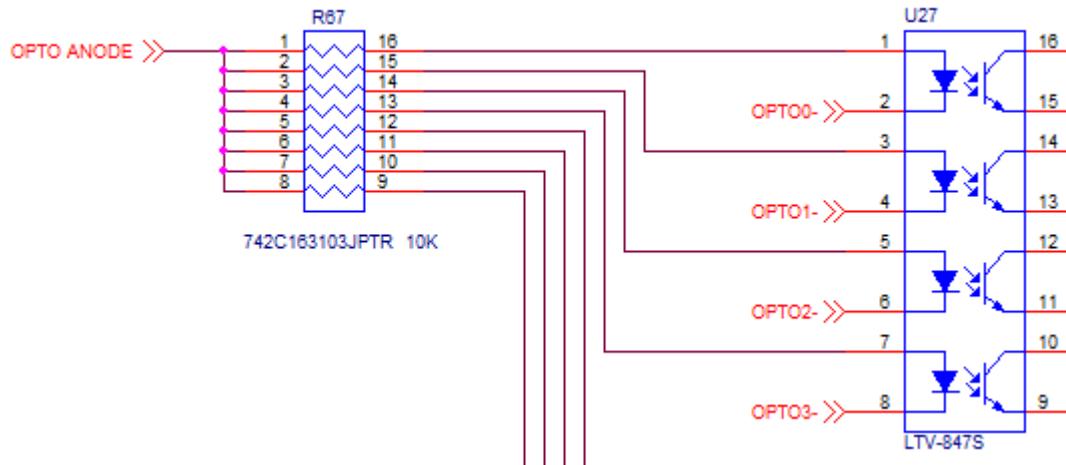

JP33 Pin	KSTEP Signal	KFLOP Related Signal
1	Relay0+	IO 0 Output
2	Relay0-	IO 0 Output
3	Relay1+	IO 1 Output
4	Relay1-	IO 1 Output
5	Analog Vcc	
6	Analog Out	IO 44 PWM Output

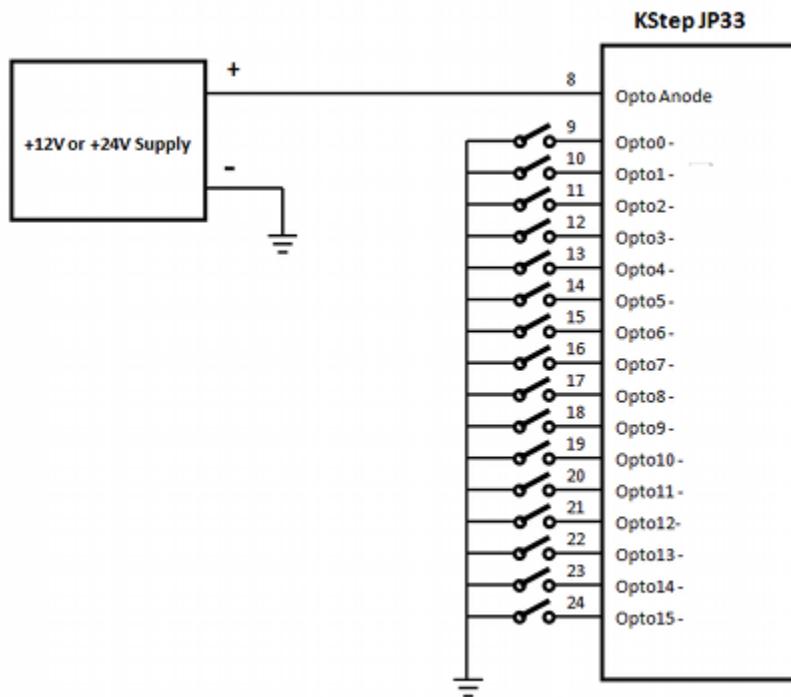

7	Analog Gnd	
8	Opto Anode	
9	Opto IN 0	IO 168 Input
10	Opto IN 1	IO 169 Input
11	Opto IN 2	IO 170 Input
12	Opto IN 3	IO 171 Input
13	Opto IN 4	IO 172 Input
14	Opto IN 5	IO 173 Input
15	Opto IN 6	IO 174 Input
16	Opto IN 7	IO 175 Input
17	Opto IN 8	IO 176 Input
18	Opto IN 9	IO 177 Input
19	Opto IN 10	IO 178 Input
20	Opto IN 11	IO 179 Input
21	Opto IN 12	IO 180 Input
22	Opto IN 13	IO 181 Input
23	Opto IN 14	IO 182 Input
24	Opto IN 15	IO 183 Input
25	Vdd +5V	+5V KFLOP (if non isolated)
26	GND KSTEP	GND KFLOP (if non isolated)

## ***Optically isolated Inputs***

The input circuit for 4 of the 16 opto inputs is shown below. Note there is a common Anode for all 16 opto inputs which is normally tied to a +12 or +24V supply. Each of the negative opto pins are then switched to ground (return for the +12 or +24V supply).

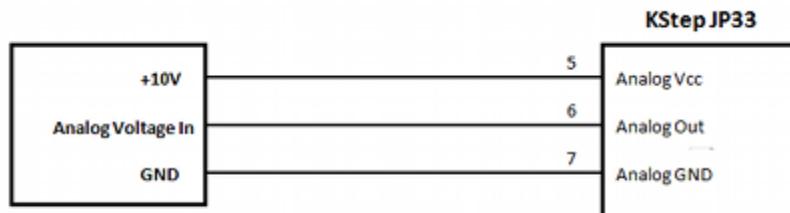

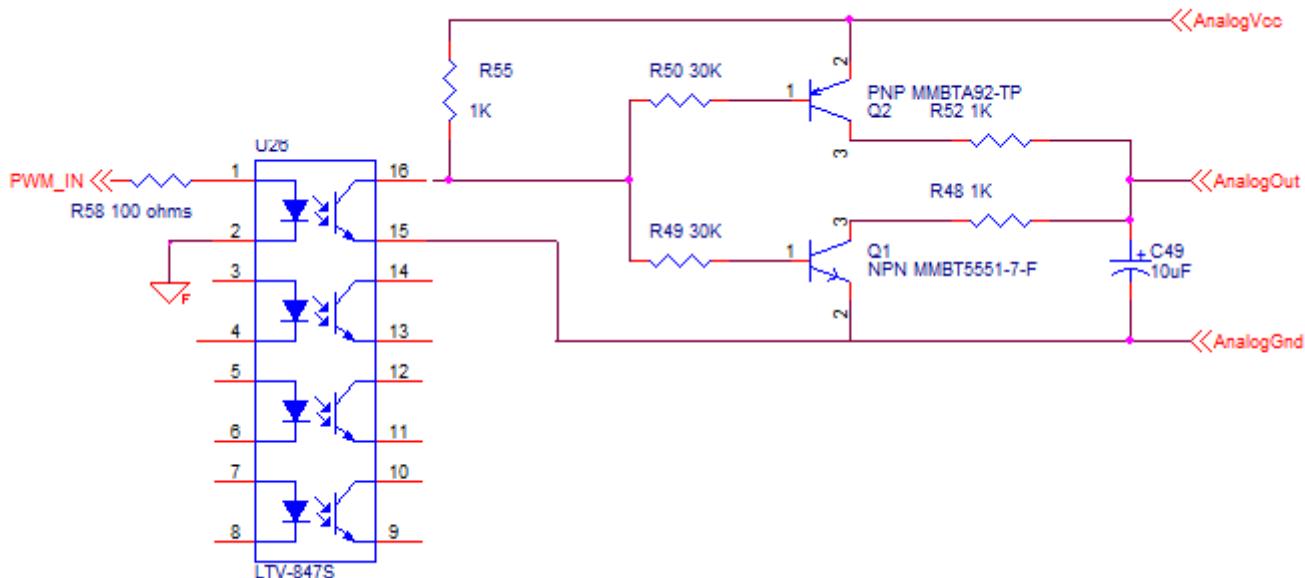

External Wiring would typically be arranged such as:

## Optically isolated PWM to Analog Circuit

A 3.3V PWM output from KFLOP IO 44 JP7 pin 5 is normally connected to KStep JP36 Pin 5 to drive the PWM to Analog circuitry. Often a VFD will have 3 input terminals where a potentiometer can be connected as speed control. The three connections AnalogVcc, AnalogOut, and AnalogGnd can be connected to perform a similar function as a potentiometer. The AnalogOut voltage will vary from AnalogGnd to AnalogVcc voltage as a function of the PWM duty cycle.

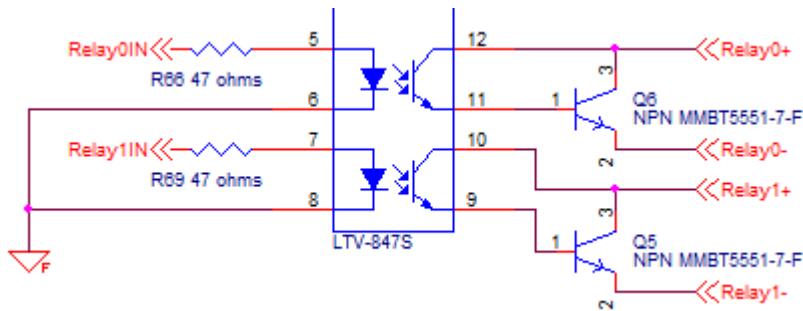

VFD Typical Speed Control Input

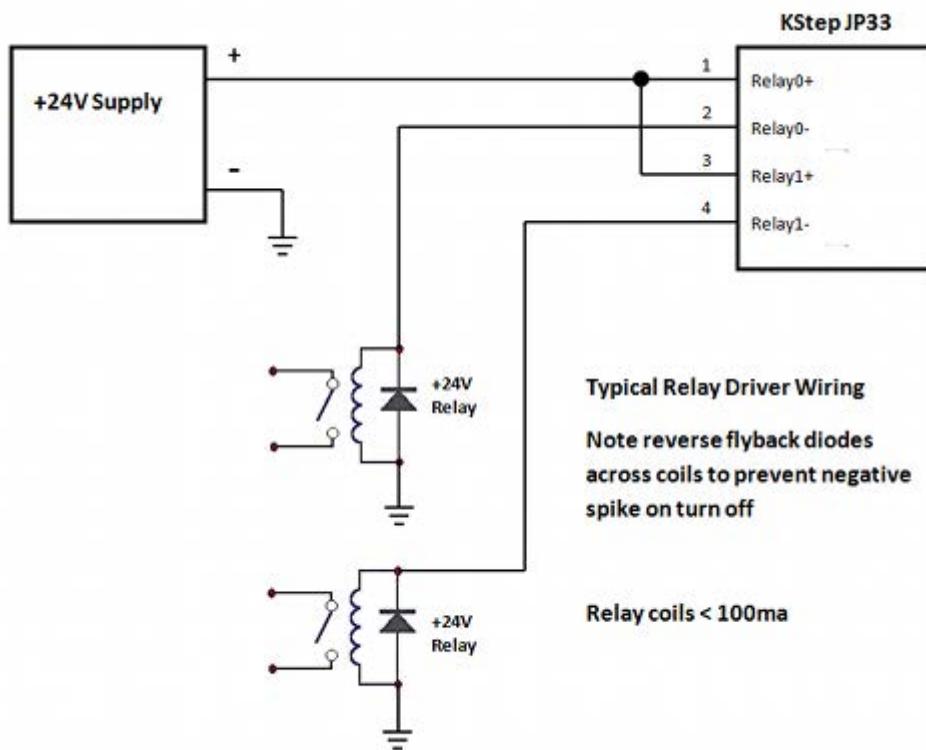

## Relay Driver Outputs

Two Optically Isolated Outputs are provided to drive medium power devices such as relay coils. Loads up to 30V @100ma may be driven.

The internal KStep circuitry is shown below which converts the incoming 3.3V LVTTL inputs to darlington transistor outputs.

A typical wiring diagram driving 24V relays.

### JP31JP32 PFD1 PFD2 Jumpers

These Jumpers can be used to control the Fast/Slow/Mixed delay settings of all 4 Motor Drives. In almost all cases these jumpers should remain removed for best performance.

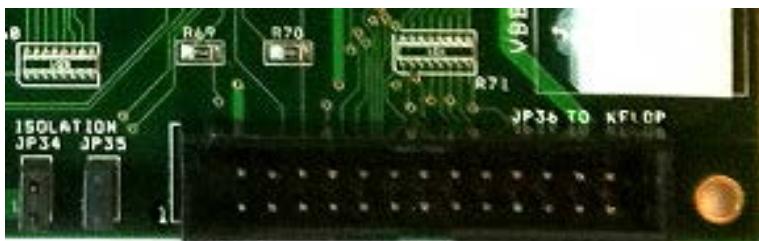

## **Current Setting Jumpers**

Current for each Stepper Coil is set with a set of 3 jumpers labeled H M L (high, medium, low).

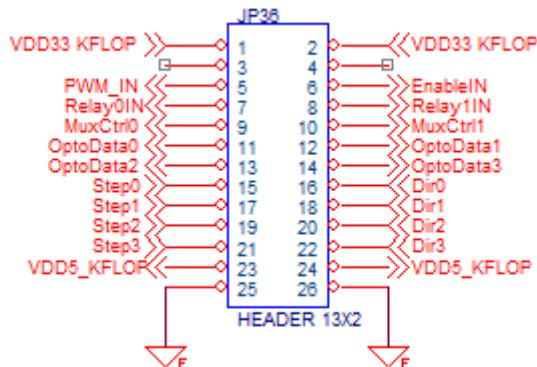

Both sets of 3 jumpers for each motor coils must be set to the same level.

H	M	L	Current (Amps)
Removed	Removed	Removed	0.63
Removed	Removed	Installed	1.25
Removed	Installed	Removed	1.88
Removed	Installed	Installed	2.50
Installed	Removed	Removed	3.13
Installed	Removed	Installed	3.75
Installed	Installed	Removed	4.38
Installed	Installed	Installed	5.00

## **JP36 To KFLOP**

JP36 is designed to connect directly to KFLOP's JP7 in a 1:1 connection. KFLOP is then able to supply the 4 sets of Step/Dir signals, the Enable, the Analog PWM signal, the 2 Relay Driver outputs, and connections for the 16 opto inputs, as well as +5V (used if running without opto isolation). To conserve KFLOP IO pins the 16 opto inputs are read back in a multiplexed fashion 4 bits at a time where 2 outputs from KFLOP select which bank of 4 are currently selected. +3.3V is also provided to power the opto multiplexing circuitry.

### ***JP34 JP35 Isolation Jumpers***

KStep allows all the Motor Power and +5V Mosfet circuitry to be totally optically isolated from the KFLOP Step/Dir and Enable signals. To operate with total isolation remove JP34 and JP35. However in this mode an additional +5V supply must be provided and applied to either J6 or JR1. With the jumpers installed KStep will make use of KFLOP +5V and KFLOP GND coming in through connector JP36 and no additional supply will be required. The [Block Diagram](#) shows how the isolation is sectioned.

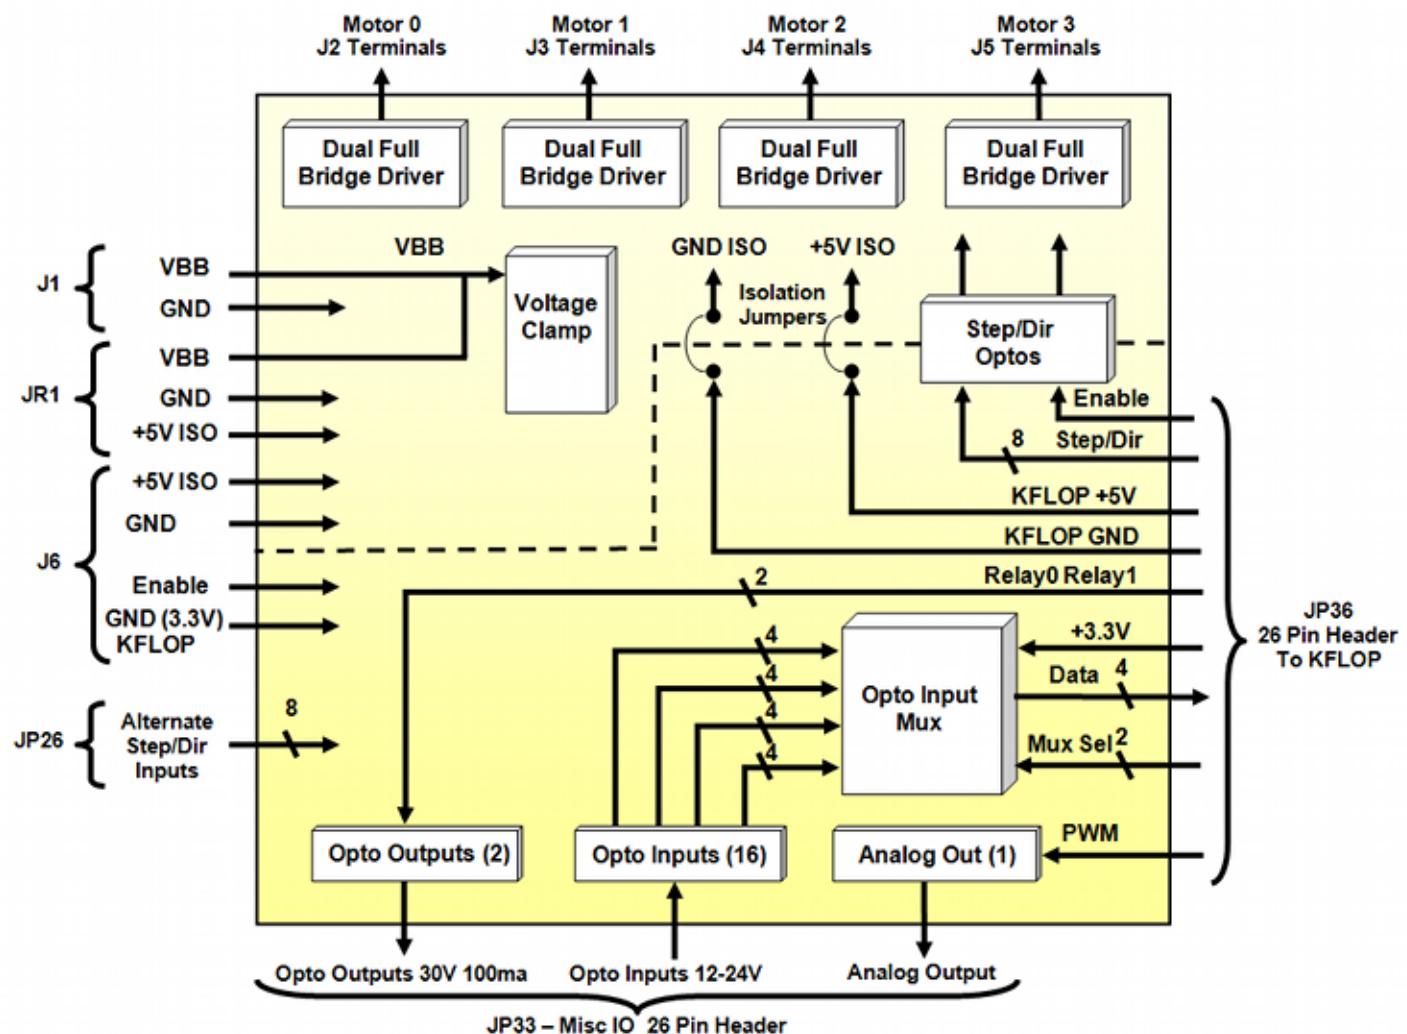

Regardless of these jumpers installed or not the 12-24V Optically isolated Inputs, the 2 Relay Driver outputs, and the Analog Output will always be fully optically isolated.

### ***J6 - GND, +5V, Enable, 3.3V GND***

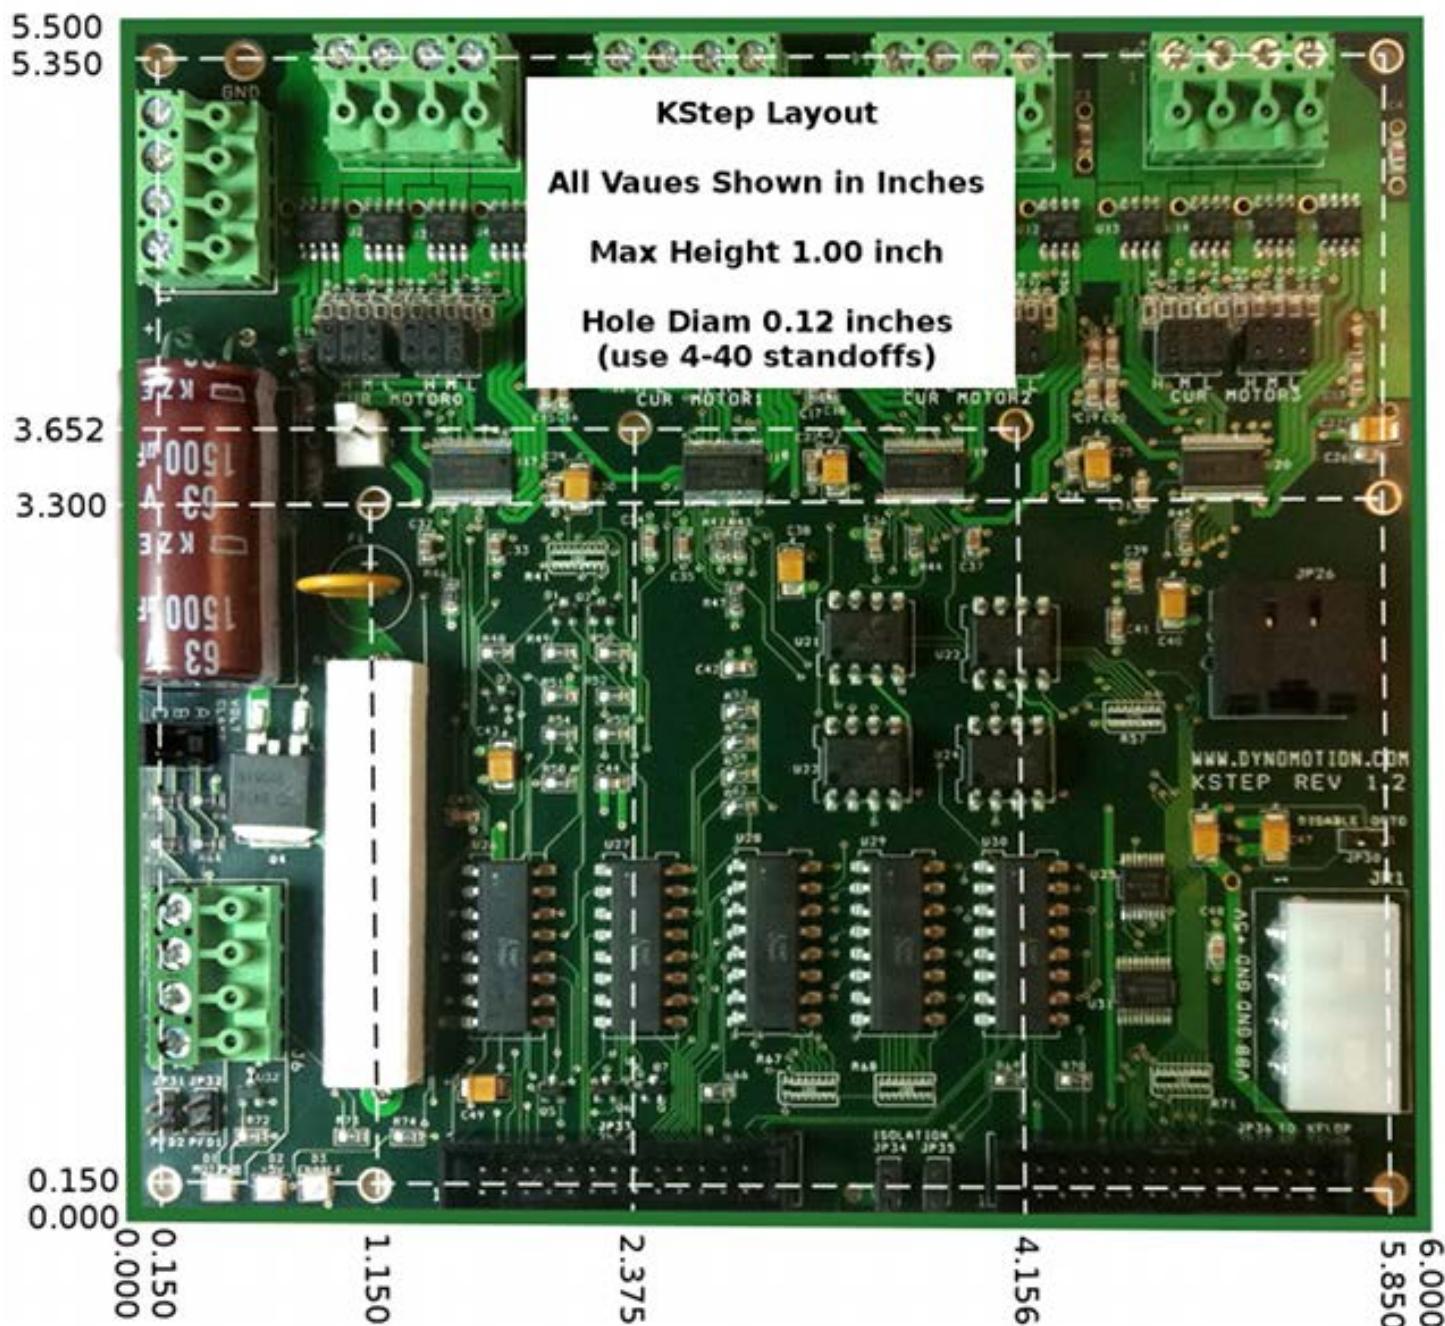

J6 provides a connection point for +5V and GND to power the KStep Mosfet Drive Circuitry if operated in Isolated mode. The Enable connection allows a means of enabling KStep amplifiers if JP36 is not used to enable the amplifiers. Controller 3.3V GND is the same GND as on JP36 which is the KFLOP or Controller Ground which is reference for the Step/Dir signals and Enable Signals. The Isolation Jumpers can be used to isolate or connect the two GND terminals on this connector.

## KStep Block Diagram

## KStep Block Diagram

## Board Layout

## Using KStep

KStep is a high efficiency 4-axis microstepping drive that can drive four motors with up to 5Amps @ 48V each. In addition to the 4 motor drives, KStep also provides additional I/O features:

- Sixteen (16) 12-24V tolerant optically isolated filtered inputs
- Two (2) optically isolated relay driver type outputs, each good for 0.1A @ 30V
- One (1) isolated PMW to Analog output

All controller signals are 3.3V/LVTTL compatible. An on-board voltage clamp circuit to protect against regenerative over voltage is also included. KStep is designed to snap together with KFLOP for easy plug and play operation. A single 26-pin ribbon cable provides all the logic, power, Step/Dir Signals, Enable, Relay driver, Analog PWM, and Optically isolated input connections between the Kstep and KFLOP boards. If necessary, two KSteps can be connected to a single KFLOP to drive a total of 8 motors.

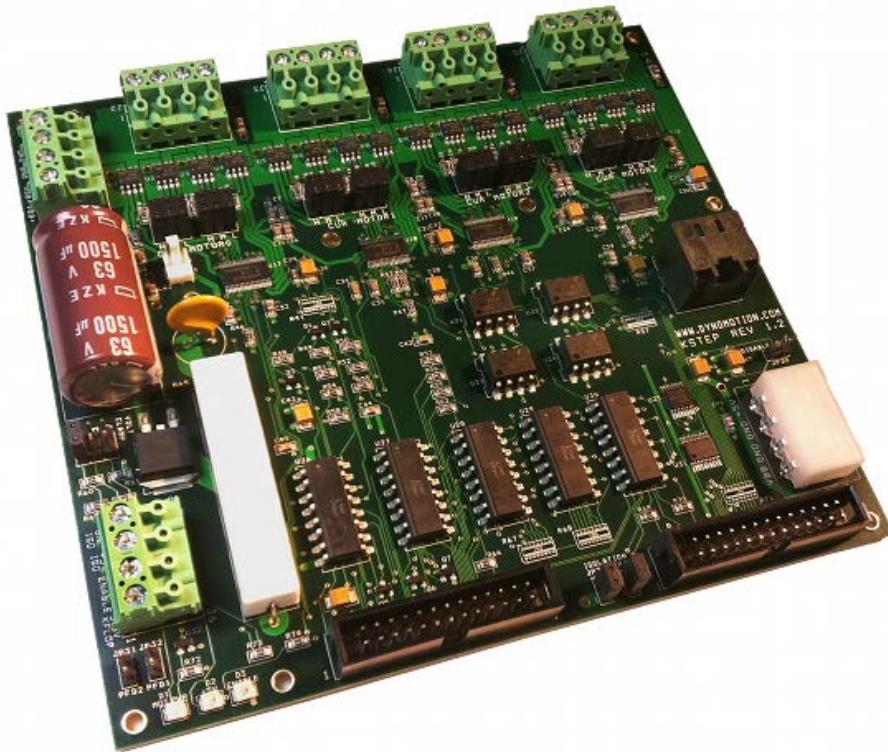

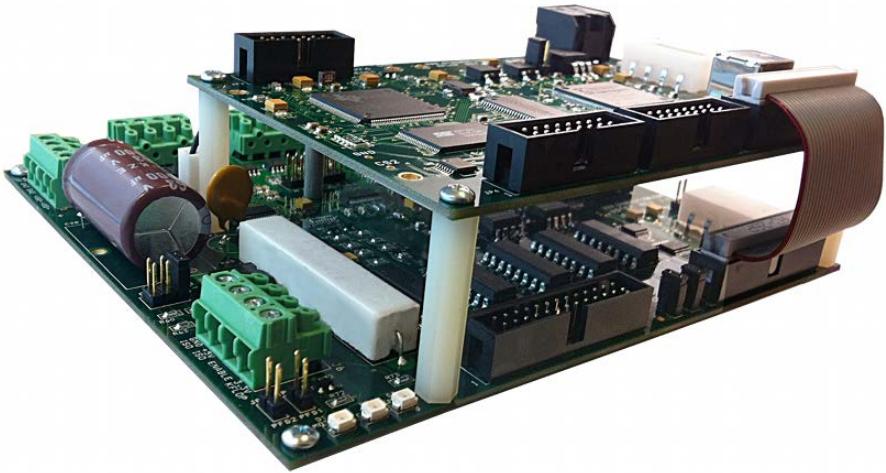

Figure 1 - Kstep

*Figure 2 – Kstep + KFLOP*

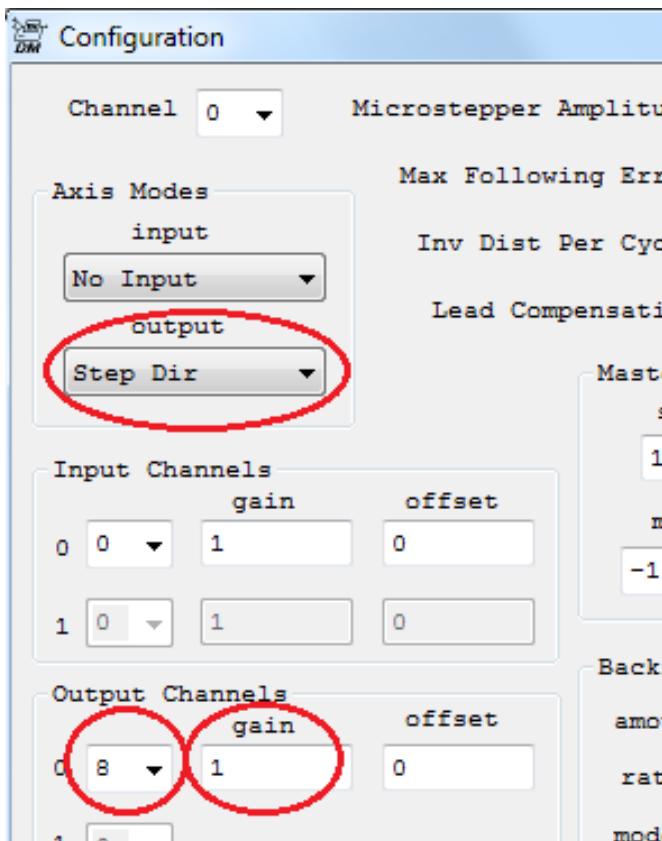

### **Configuring KFLOP for use with KStep**

Configuring KStep is fairly straightforward, as it is normally used in an open loop system (although it is possible to operate in [closed loop stepper mode](#)) so all feedback, servo, PID, Filter, Feedforward and commutation parameters are not used and can be ignored. KStep is effectively a [Step/Dir](#) driver, so it makes use of the Step/Dir Output mode in KFLOP (See the items circled in red below - Note that output mode type "Step Dir" is selected). The screen shown is the Output Channel selection for KStep Motor channel #0. Note that output channel 8 is selected instead of 0 as you might assume. As KStep requires a LVTTL signal, rather than using Output channels 0 through 4, Output channels 8 through 11 respectively should be used instead, as they provide a LVTTL signal. See [here](#) for more information. An output gain of -1 may be specified to reverse the direction of motion.

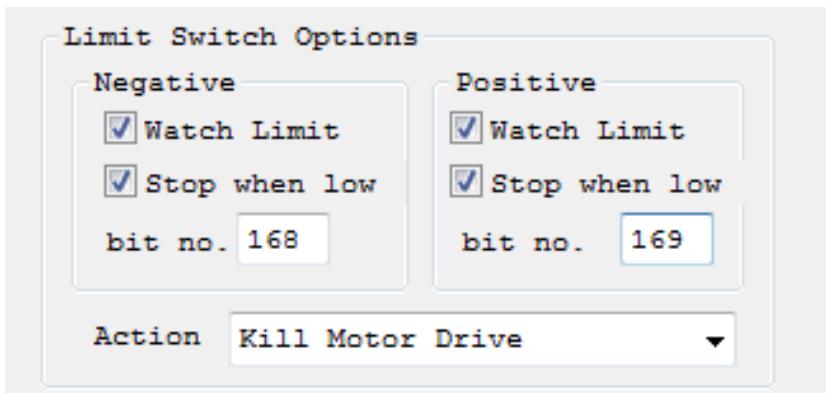

Note: for the pulse polarity and pulse time to be set properly, the following line of C Code needs to be executed after every power up. `FPGA(STEP_PULSE_LENGTH_ADD) = 63 + 0x80; // set polarity and pulse length to 4us` When using the default settings, there is marginal timing on direction setup which may result in "drift" caused by a microstep in the wrong direction when changing directions. This line of Code is already included in the Example C Initialization Programs (i.e. `InitKStep3Axis.c`)

```
FPGA(STEP_PULSE_LENGTH_ADD) = 63 + 0x80; // set polarity and pulse length to 4us
```

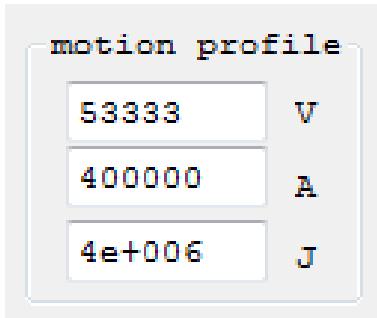

Example Axis configurations are also provided as `KStepAxis0.mot`, `KStepAxis1.mot`, `KStepAxis2.mot`, `KStepAxis3.mot`

Example Axis configurations are provided in the C:\KMotion431\KMotion\Motors directory (assuming a default install location). KStepAxis0.mot, KStepAxis1.mot, KStepAxis2.mot and KStepAxis3.mot are the most basic configurations. Limit switch options are also configured on this screen. KStep's optically isolated 12-24V Inputs are commonly used to connect Limit switches and are referenced as Input Bits 168 through 183 inclusive. If you are using NC (normally closed) type limit switches, this means that the inputs are normally high and become low when activated. In this case the "Stop when low" option should be selected. If using NO (normally open) type limit switches, this means the inputs are normally low, and become high when activated. In this case, the "Stop when low" option should be cleared. For more info see [here](#).

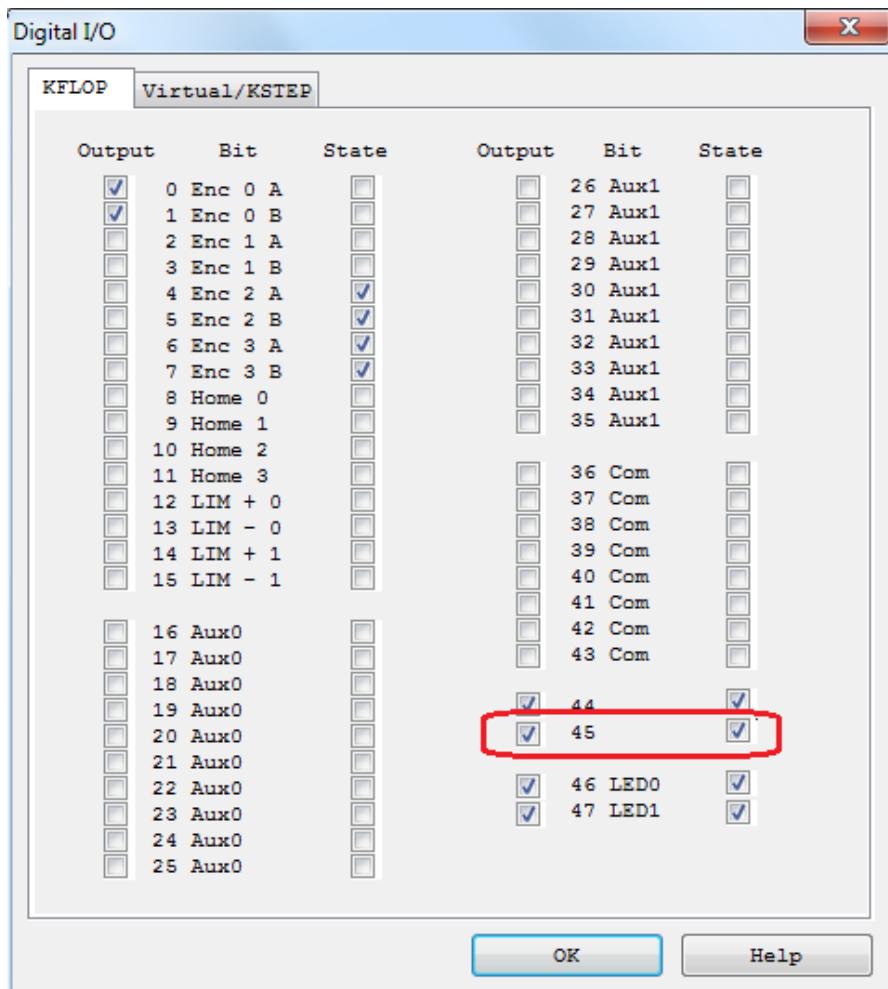

Motion profile settings on the Step Response Screen are used

### ***Enable KStep Amplifiers***

An amplifier enable signal is required to enable the KStep Full Bridge Amplifiers. One signal enables all four of the KStep amplifiers. The enable signal is positive true, meaning the drives are enabled when a 3.3V LVTTL (sourcing) signal is received. When using a 26-pin ribbon cable to connect KStep (JP 36) and KFLOP (JP 7), this signal is routed to KFLOP's IO 45, which must be set as an output, and also set high to enable the drives. Note that the enable signal is only optically isolated from VBB and GND when KSTEP is in isolated mode.

If JP36 is not being used to connect KFLOP to KStep, then a 3.3V enable signal may be applied to a screw terminal on J6 instead. If two KSteps are being used (for driving 8 motors), then the screw terminals on J6 should be used as an output on the first KStep to daisy chain the enable signal to the second KStep.

For testing purposes KStep may be enabled using the Digital I/O Screen as shown below.

From C code the Amplifiers can be enabled with the following code.

```
SetBitDirection(45,1); // set Enable Signal as Output
SetBit(45);           // Enable the KStep Amplifiers
```

It's possible to write code to enable the amplifiers as soon as motion is detected and disabled after a period of time with no motion. Here is an example:

```
double T0, LastX=0, LastY=0, LastZ=0;
for (;;) // loop forever
{
```

```

WaitNextTimeSlice();

// Service Amplifier disable after no activity for a while
if (ch0->Dest != LastX || ch1->Dest != LastY || ch2->Dest != LastZ)

{
    // we moved - enable KStep Amplifiers
    SetBit(45);

        T0 = Time_sec(); // record the time and position of
last motion

        LastX=ch0->Dest;
        LastY=ch1->Dest;
        LastZ=ch2->Dest;

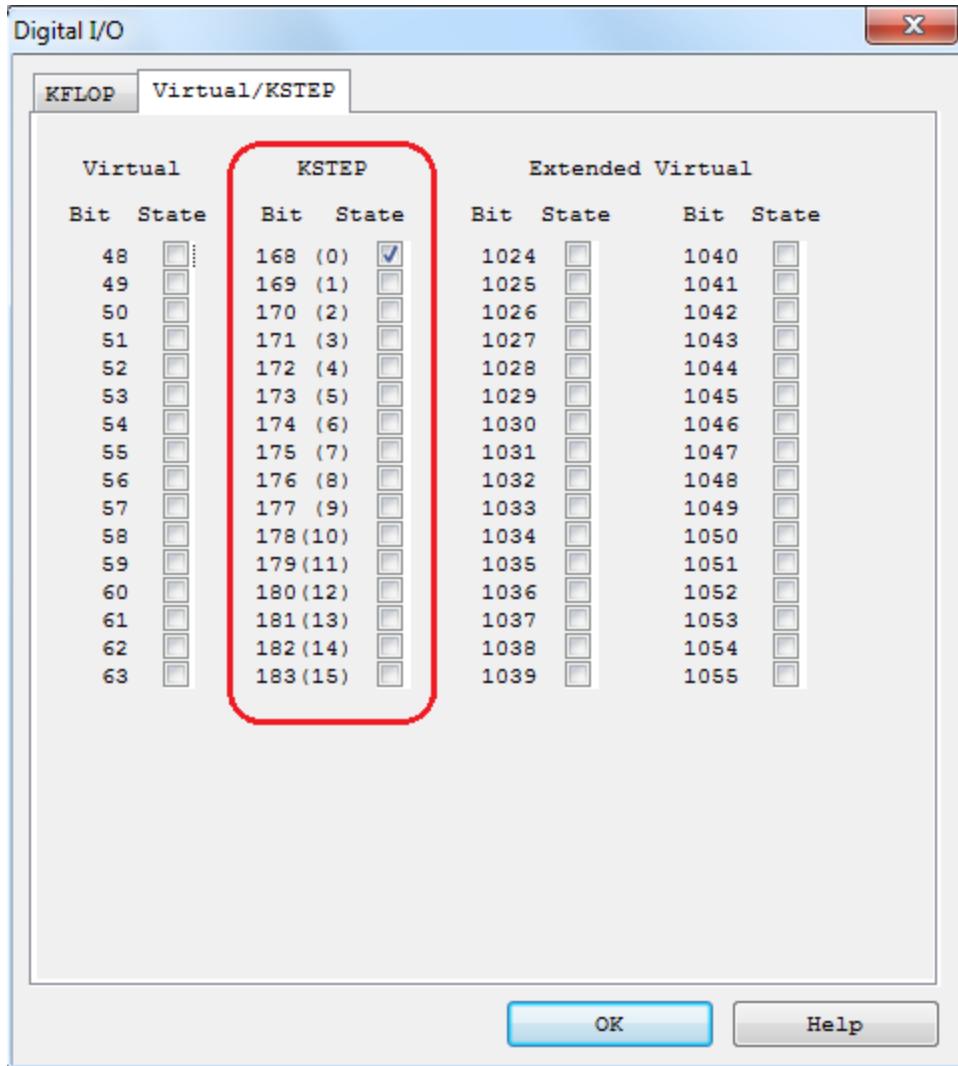

}
else
{
    if (Time_sec() > T0 + 10.0) ClearBit(45);
}
}

```

## Digital Status

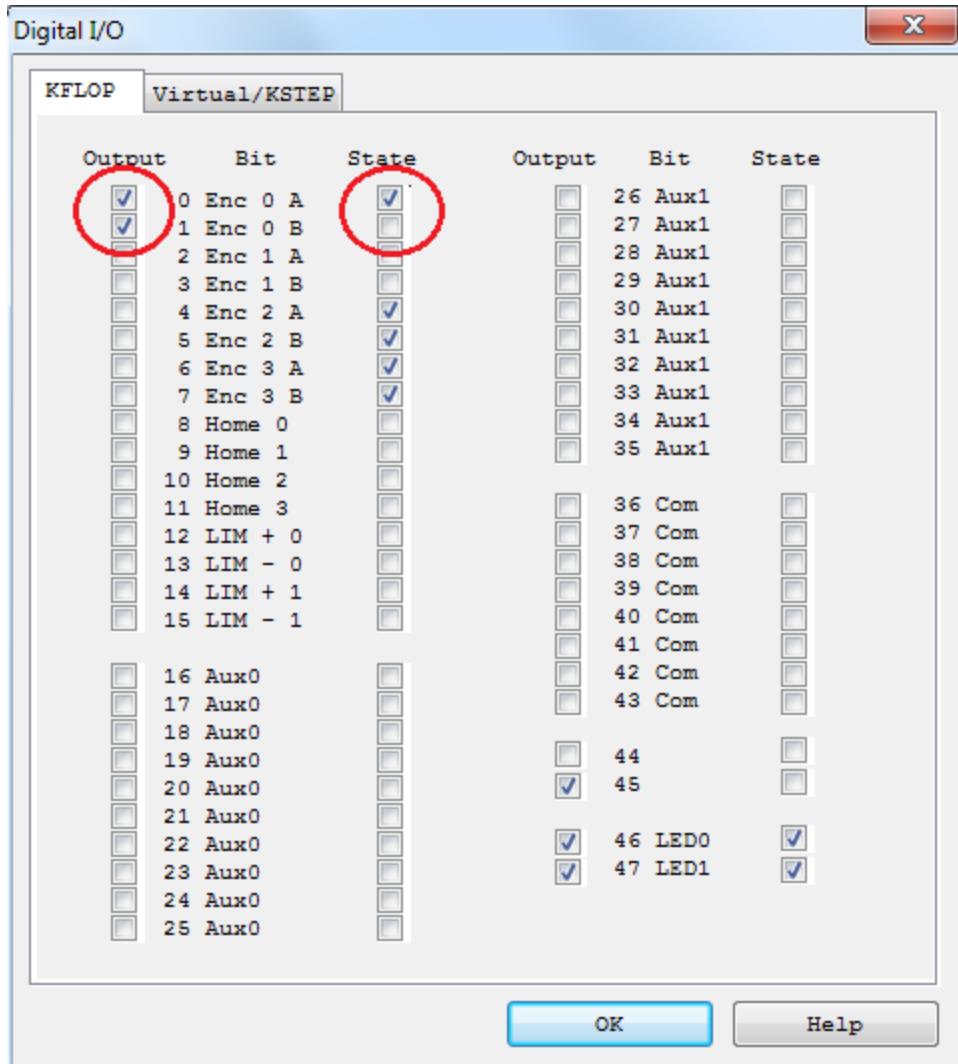

The state of the Optically Isolated 12-24V Digital Inputs can be observed by selecting the "Virtual/KSTEP" Tab on the Digital I/O Screen. Each input will be marked as active if current is flowing through the optical isolation circuit. For input circuits and pinouts [see here](#). The KStep Opto Inputs are actually virtual inputs that are multiplexed in through KFLOP I/O. KFLOP can perform this multiplexing automatically by setting the global variable **KStepPresent**. The following line of C code should be added to your Init.c program:

```
KStepPresent=TRUE;
```

## ***Relay Driver Outputs***

The Optically Isolated 24V outputs can be observed and controlled by selecting the KFLOP tab on the Digital I/O Screen. Each output will be marked as active if current is flowing through the optical isolation circuit. The KStep outputs are the same as the standard KFLOP outputs except they are optically isolated and amplified to handle up to 24V. For output circuit and pinouts [see](#).

To make use of the outputs within a C program the following C code shows an example of enabling both the outputs, turning them on, then turning them off.

```

SetBitDirection(0,1); //set as output
SetBitDirection(1,1); //set as output

SetBit(0); // turn output on
SetBit(1); // turn output on

ClearBit(0); // turn output off
ClearBit(1); // turn output off

```

## ***Connecting and Using 2 KSteps***

Connect the RJ45 cable between KFLOP JP5 and KStep#2 JP26. KFLOP's Step/Dir Generators 4-7 will then be connected to KStep#2. Configure as OutputChan0 12-15 to drive in TTL mode as required by KStep.

You will also need to provide power, GND, and Enable to KStep. The simplest method is usually to connect the 4 pins on J6 between the 2 KSteps.

Click here for more [images](#).

## ***Analog Output***

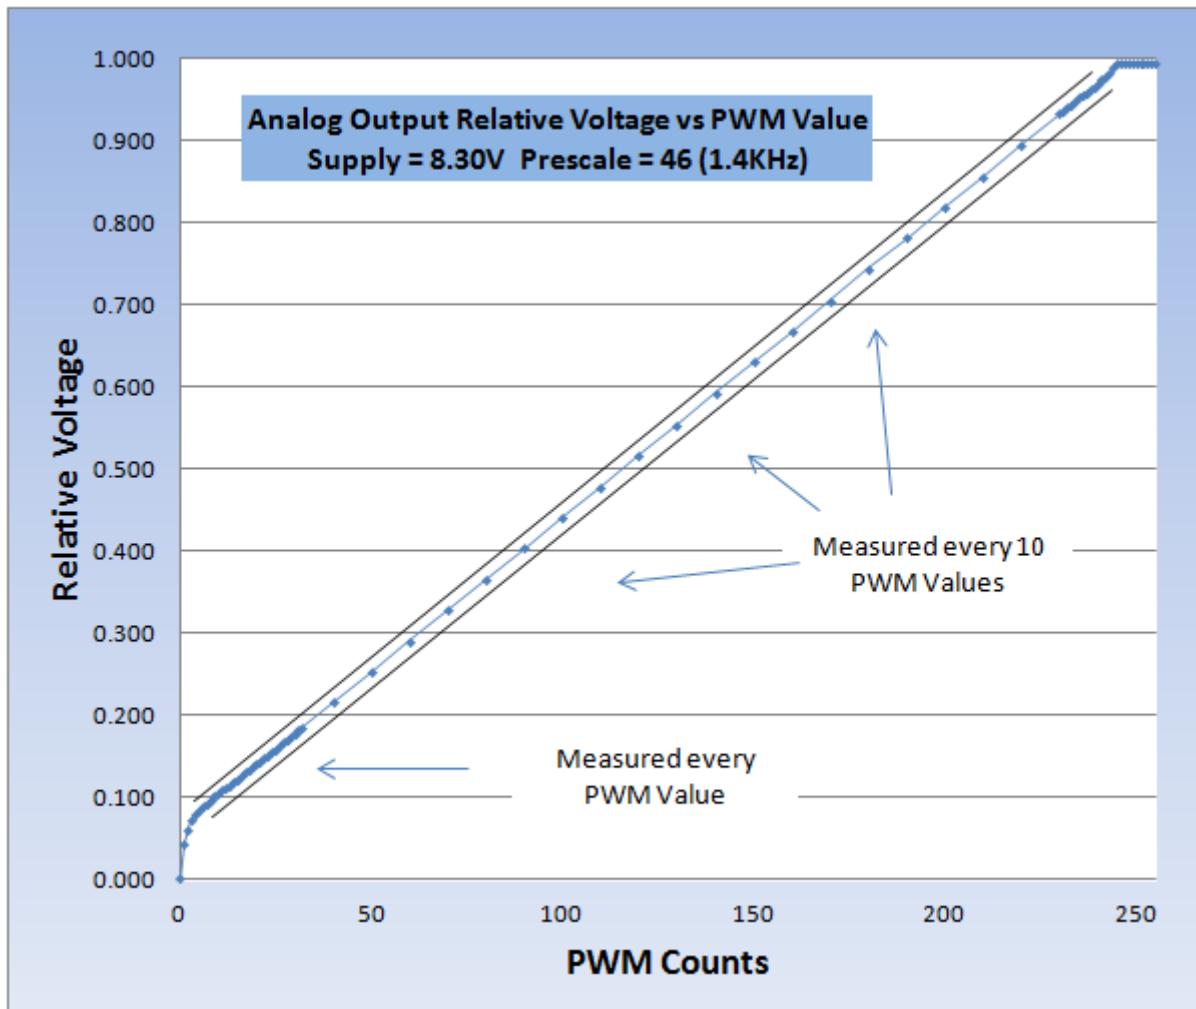

The KStep Analog output is a low Speed (10ms time constant) isolated analog output that is commonly used as a VFD Spindle Speed Control signal. KFLOP outputs a 3.3V digital PWM on IO 44 to KSTEP which optically isolates and filters it to create an analog signal. Isolated power and ground (often supplied by the VFD) are required. The analog output voltage will be a proportion of the supplied voltage relative to the duty cycle of the PWM signal. For example a 75% high duty cycle will provide a voltage which is approximately 75% of the supplied voltage.

To configure KFLOP to output the appropriate PWM signal into KSTEP the configuration code below should be used. There is an FPGA option to move PWM0 (which normally is output on connector JP6 with the other 7 PWM outputs) over to JP7 Pin5 IO 44. IO 44 must be configured as an output; the PWM Prescale dividers set to a reasonable value (like?), and then enable PWM.

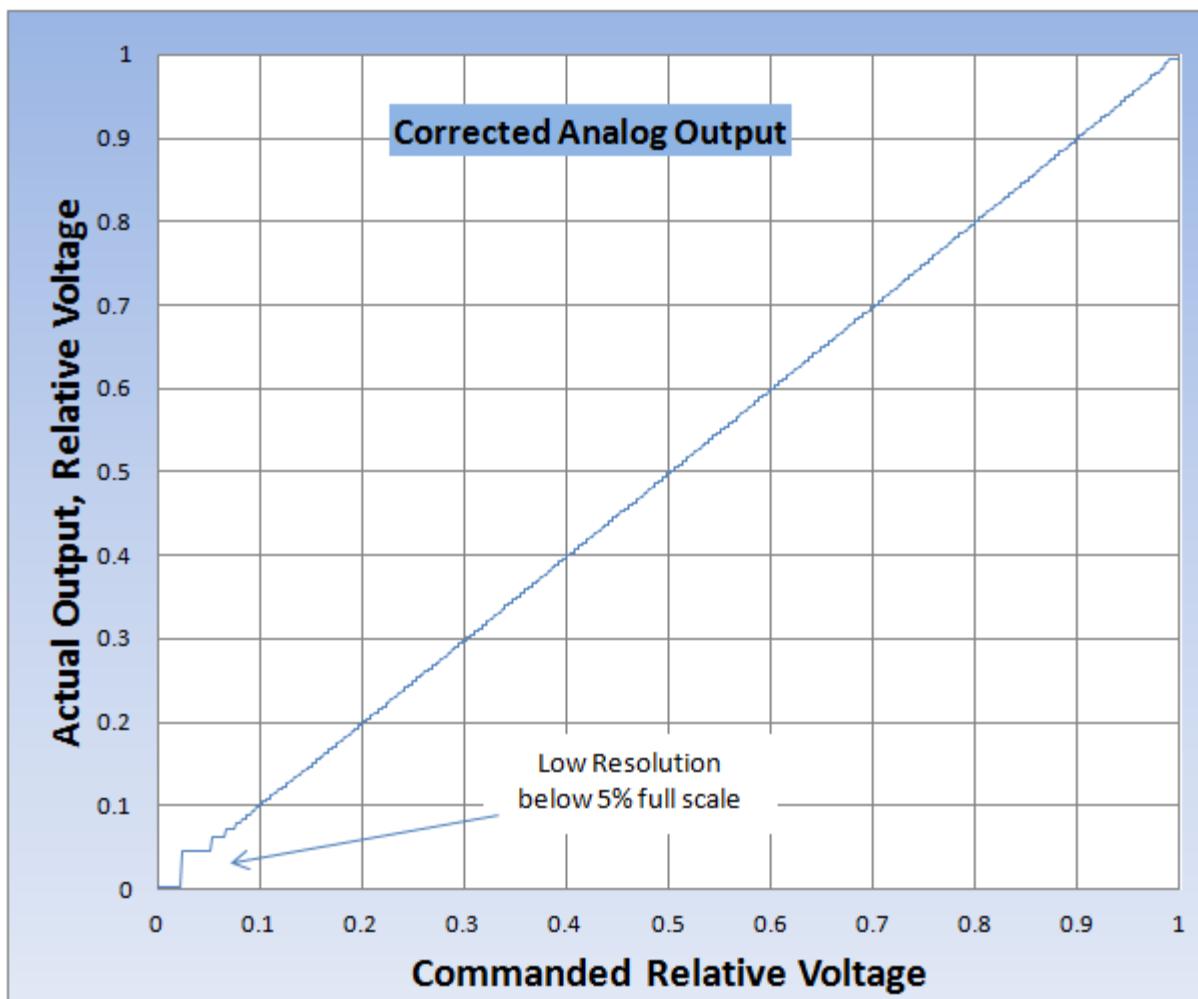

```
FPGA(KAN_TRIG_REG)=4; // Mux PWM0 to JP7 Pin5 IO 44 for KSTEP
SetBitDirection(44,1); // define bit as an output
```

```
FPGA(IO_PWMS_PRESCALE) = 46;           // divide clock by 46 (1.4 KHz)
FPGA(IO_PWMS+1) = 1;                   // Enable
```

The Analog output has nonlinearity near the 0% duty cycle region due to opto coupler pulse shaping effects. The nonlinearity can be mostly corrected in software through calibration. Below is a raw uncorrected analog output with a PWM frequency of 1.4KHz (PWM Prescale = 46).

Using a correction algorithm where the PWM value that will most closely produce the desired output voltage is determined from a table lookup approach for the first 7 PWM counts, and a simple linear interpolation is used for determining PWM settings 7 through 240 the linearized results are shown below. Although the signal is now linear, the resolution is low for settings below ~5% full scale.

Below is the C function used to linearize the output.

```

// PWM->Analog Correction
//
// assume very non-linear for first few count and linear thereafter
//
// Measure output ratio for first 0-7 counts then at 240

float V[ ]=
{
0.001, // count = 0
0.031, // count = 1
0.044, // count = 2
0.054, // count = 3
0.062, // count = 4
0.069, // count = 5

```

```
0.074, // count = 6
0.079 // count = 7
};

float V240=0.970;

int CorrectAnalog(float v)
{
    int r;
    float v2=2.0f*v;
    // compare with half way points to determine closest count
    if (v2 < V[1]+V[0]) return 0;
    if (v2 < V[2]+V[1]) return 1;
    if (v2 < V[3]+V[2]) return 2;
    if (v2 < V[4]+V[3]) return 3;
    if (v2 < V[5]+V[4]) return 4;
    if (v2 < V[6]+V[5]) return 5;
    if (v2 < V[7]+V[6]) return 6;

    // must be 7 or higher do linear interpolation

    r = (int)(7.5 + (v-V[7])/(V240-V[7])* (240.0f-7.0f));
    if (r>255) r=255;
    return r;
}
```

## KStep Basics Tutorial

### Introduction

KSTEP is an add-on stepper driver for KFLOP and it is perhaps the easiest way available to start controlling stepper motors.

This guide will help you with the most basic KSTEP setup so that by the end of these instructions you will be able to control stepper motors using the KMotion setup/configuration screens, C-Code and G-Code. This guide is not comprehensive, however, and you should spend time reading the help pages for more in-depth information:

1. Main manuals page: <http://dynomotion.com/Help/index.htm>
2. KFLOP Connectors: <http://dynomotion.com/Help/SchematicsKFLOP/ConnectorsKFLOP.htm>
3. KSTEP Connectors: <http://dynomotion.com/Help/SchematicsKStep/ConnectorsKStep.htm>
4. KSTEP Use and Settings: <http://dynomotion.com/Help/SchematicsKStep/UsingKStep.htm>
5. KSTEP Block Diagram: <http://dynomotion.com/Help/BlockDiagramKStep.htm>
6. KSTEP Specifications: <http://dynomotion.com/Help/SpecificationKStep.htm>
7. Yahoo Groups Forum (research and ask questions here):  
<https://groups.yahoo.com/neo/groups/DynoMotion/info>
8. CNC Forum (research and ask questions for CNC-specific applications here):

### KSTEP Tutorial Table of Contents:

1. Basic Software Setup
2. Basic Hardware Setup
  - A. Providing +5V Board Power
  - B. Checking Firmware Version
  - C. Voltage Clamping
  - D. Power Supply input
  - E. Current Settings
  - F. Basic Motor Wiring
3. Driving Your Steppers
  - A. Enabling Output
  - B. Setting Axis/Channel Parameters and Running an Initialization C Program (Init)
  - C. The Four Requirements for an Init C Program
  - D. Use KMotionCNC to Jog Your Motors

What you need:

1. KFLOP/KSTEP or KFLOP/2xKSTEP combo with provided hardware
2. Dedicated 12V-48V Motor Power Supply to be wired into KSTEP as described below.  
Optional +5V power supply.
3. Stepper Motors
4. USB Cable (included with every KFLOP and KFLOP combo order)
5. Ohm Meter (or multi-meter)
6. General tools for electronics (wire cutters/strippers, small screwdrivers, etc.)

## **1. Software Setup**

Start by ensuring you have the latest KMotion software installed on your computer. Download and install the latest KMotion software from [This Software Download Page](#). Ensure the software installs and starts normally. If the software does not install properly, search the [Yahoo](#) or [CNC Zone](#) forums for help on common installation issues such as temporarily disabling antivirus software installation preventions, or [enabling Windows unsigned software installations](#).

Note: Every screen in KMotion has a 'Help' button that will bring up a Help page that is focused on that particular screen.

## **2. Hardware Setup**

### **2A. Providing +5V Board Power**

In a static-free environment, remove your KFLOP and KSTEP from the packaging and connect the two [as shown here](#). The first step to powering up KFLOP is to determine how to provide the +5V used to power the boards. Both KFLOP and KSTEP require +5V for operation and there are a number of ways to provide it.

**Note:** Once +5V is supplied to the boards, it is available at every +5V terminal. Therefore do not supply +5V by more than one way or you will damage the boards and potentially your power supplies. The only exception to this is if KFLOP and KSTEP are isolated by removing jumpers on KSTEP JP34 and JP35. With this isolation, +5V must be supplied to both KFLOP and KSTEP as described below.

With jumpers installed on KSTEP's JP34 and JP35, the +5V and GND signals will be shared between both boards and only needs to be supplied in one way. The possibilities are:

1. On KFLOP: Through the USB cable plugged into KFLOP. The jumper on KFLOP's J3 must be installed for power to be received through the USB cable and the jumpers on KSTEP's JP34 and JP35 must be installed for KSTEP to receive the +5V signal. If board power is supplied this way, ensure +5V is not provided through KFLOP's JR1, KSTEP's JR1, or

KSTEP's J6 connectors or the board and power supply could be damaged. Note that the USB cable should be of high quality and must meet USB 2.0 specifications for plug shell-to-shell resistance of <0.6 Ohms. When measuring resistance, remember to subtract the resistance introduced by the measuring device by first measuring the probe-to-probe contact resistance.

2. On KFLOP: +5V and GND through KFLOP's JR1 Molex® connector. The jumper on KFLOP's J3 must be removed to avoid receiving +5V from the USB cable in this case. The jumpers on KSTEP's JP34 and JP35 must be installed for KSTEP to receive the +5V signal - in this case do not provide +5V on KSTEP's JR1 or J6 connectors. Note that in this case, the +12V provided through the Molex connector is not used internally, but is routed to pins on the JP4, JP6, and JP7 connectors for convenience.
3. On KSTEP: +5V and GND through KSTEP's JR1 Molex connector. The jumpers on KFLOP's J3 must be removed and the jumpers on KSTEP's JP34 and JP35 must be installed in this case in order for KFLOP to receive +5V power. Also note that if KSTEP's JR1 Molex connector is used, it is likely that +12V is being provided through this connector and therefore all VB connections on KSTEP will have 12V applied to them, and which would then be used for motor power. Therefore, do not provide motor power through KSTEP's J1 terminal.
4. On KSTEP: +5V and GND through KSTEP's J6 terminal block. The jumpers on KFLOP's J3 must be removed and the jumpers on KSTEP's JP34 and JP35 must be installed in this case in order for KFLOP to receive +5V power.

In the case where you want KFLOP and KSTEP to have +5V supplied independently. Remove jumpers on KSTEP's JP34 and JP35 and then supply power through 1 or 2 and 3 or 4 above. Note that, in this case, the +5V power supplies should be different power supplies or the purpose of supplying board power independently is defeated.

Once the board power delivery method is determined, the boards are ready to power up. Provide +5V via your chosen method to power up the boards.

On power up, KFLOP LEDs will illuminate as will the "+5V" LED on KSTEP indicating that both boards are receiving a +5V signal. Once motor supply power is fed into KSTEP as described below, the "MOT PWR" motor supply LED on KSTEP will illuminate.

## 2B. Check the firmware version and update if necessary

Next, ensure the software version on KFLOP is up-to-date. In the KMotion software, open the Console screen and type the command "Version" into one of the command lines (if one of the command lines already contains the command there is no need to type it). Press the "Send" button next to the command to send the Version Command to KFLOP to display the version of onboard firmware. If the firmware version does not match the version of KMotion you downloaded and are running (Help>About KMotion...), open the Config screen and press the "New Version" button. The pop-up window will automatically locate the necessary file for the software update, click "Open" and confirm the next pop-up. Allow a few seconds for the software to finish updating and after it is finished, cycle power to KFLOP.

## 2C. Motor Power Supply Setup - Voltage Clamping

Voltage spikes due to Regenerative Braking and other sources can potentially raise the supply voltage up to a level that can damage electronics including KSTEP or the power supply. Voltage Spikes may also cause a power supply to trip a fault and shut down. KSTEP's Voltage clamp can be used to avoid these problems.

Motor power supply may be supplied through KSTEP's J1 terminal block OR KSTEP's JR1 Molex connector, but not both at the same time; and it is crucial that voltage clamps on KSTEP are set according to the motor power supply voltage level. KSTEP can handle motor power supplies from 12V to 48V and voltage clamp settings are designed to be 1V higher than common power supply voltages. **It is critical that you clamp voltage on KSTEP at a value HIGHER than the motor power supply.**

See this image for voltage clamp jumper location: [KSTEP Connector Pinouts](#)

Common power supply voltages are 12V, 24V, 36V, and 48v. KSTEP has a voltage clamping feature that can be set to 13V, 25V, 37V, or 49V volts. So whatever is the value of your motor power supply voltage, set the clamp to the next value higher than your motor power supply. **Setting the voltage clamp to a value lower than the power supply will draw excessive current and is likely to cause damage to your KSTEP and/or the power supply.**

Pin jumpers are provided with every KSTEP purchase. These are small plastic rectangular pieces with a metal coupling inside that connects two pins together when applied. You will use these to set the voltage clamp. Essentially, every jumper added to A, B, or C of the voltage clamping pins will reduce the voltage clamping by 12V. So, with no jumpers, voltage is clamped at 49V. With a jumper on A, voltage is clamped at 37V. With jumpers on A and B, voltage is clamped at 25V. With jumpers applied to A, B, and C, voltage is clamped at 13V (the lowest setting). Make sure voltage is clamped **HIGHER** than your power supply voltage or you will damage KSTEP.

Motor Power Supply Voltages	Required Number of Jumpers	Jumper Location	Clamping Level
37V to 48V	None	-	49V
25V to 36V	1	A	37V
13V to 24V	2	A+B	25V
12V Only	3	A+B+C	13V

## 2D. Motor Power Supply Setup - Connecting Motor Power to KSTEP

There are two ways to feed motor power into KSTEP, and they are incompatible with each other such that you must choose one or the other and not both or you will damage your power supplies and KSTEP.

The first and perhaps easiest way to connect motor power is through the Molex connector at position JR1 on KSTEP. Many power supplies have this standard connector and it plugs easily into KSTEP to provide motor power. **Caution:** Note that if JR1 is plugged into a power supply this way, all VB connections on the board will have that voltage active on them. Also, it is likely that +5V signals are provided by a power supply with this connector and so you need to make sure no other 5V signals are being provided as described in the Board Power section of this tutorial before plugging power into the board in this way.

The second way to supply motor power is through the screw terminals at position J1 on KSTEP. For applications requiring less than 10 Amps, simply screw in power supply leads into one of the respective VBB+ and GND terminals on J1. Do not supply power through JR1 if you supply power on J1 or you will damage KSTEP and your power supply.

Note: for applications requiring more than 10 Amps, both of the VBB and GND connections on J1 should be used.

Power Supply Voltage Selection is a fairly complex subject but as a rule-of-thumb the supply should be 10~15 times higher than the rated voltage of the steppers. Sometimes the voltage of the Stepper motor is not stated, in which case it can be determined by using Ohm's law ( $V = I \times R$ ) and the Current and Resistance specifications. For example, for a 3 Amp motor with a resistance of 0.6 ohms the motor would require 1.8V. A power supply of 18V to 27V might be used.

## 2E. Motor Current Settings

The current supplied to your motors must be configured to provide the correct level and KSTEP provides a physical method of doing this through the installation of jumpers on current setting pins on KSTEP.

Stepper motor current is generally specified on a per coil basis such as 670mA, or 0.67A, per coil. It is important to know what is the current per coil for your motors so you can set the correct current jumpers on KSTEP. The current setting pins are labeled on the board as "CUR MOTOR#" where # is the axis number from 0-3. KSTEP has a High, Medium, and Low current jumper for each motor coil (2 coils per axis). Set jumpers on the H (high), M (medium), and L (low) pins such that the value is the next level lower than your motor specifications. For example, if your motor has a per coil current rating of 670 mA, you will not set any jumpers for both coils - corresponding to a current setting of 0.63A. For a motor with a 3.5A current per coil specification you would set jumpers on H for both coils corresponding to a current setting of 3.13A.

Use the table below to determine how to set your jumpers according to the motor current ratings.

<b>Motor Current per Coil Rating (Amps)</b>	<b>H</b>	<b>M</b>	<b>L</b>	<b>Current Setting (Amps)</b>
0.63 to 1.24	Removed	Removed	Removed	0.63
1.25 to 1.87	Removed	Removed	Installed	1.25
1.88 to 2.49	Removed	Installed	Removed	1.88
2.50 to 3.13	Removed	Installed	Installed	2.50
3.13 to 3.74	Installed	Removed	Removed	3.13
3.75 to 4.37	Installed	Removed	Installed	3.75
4.38 to 4.99	Installed	Installed	Removed	4.38
5.00+	Installed	Installed	Installed	5.00

## 2F. Wiring Motors to KSTEP

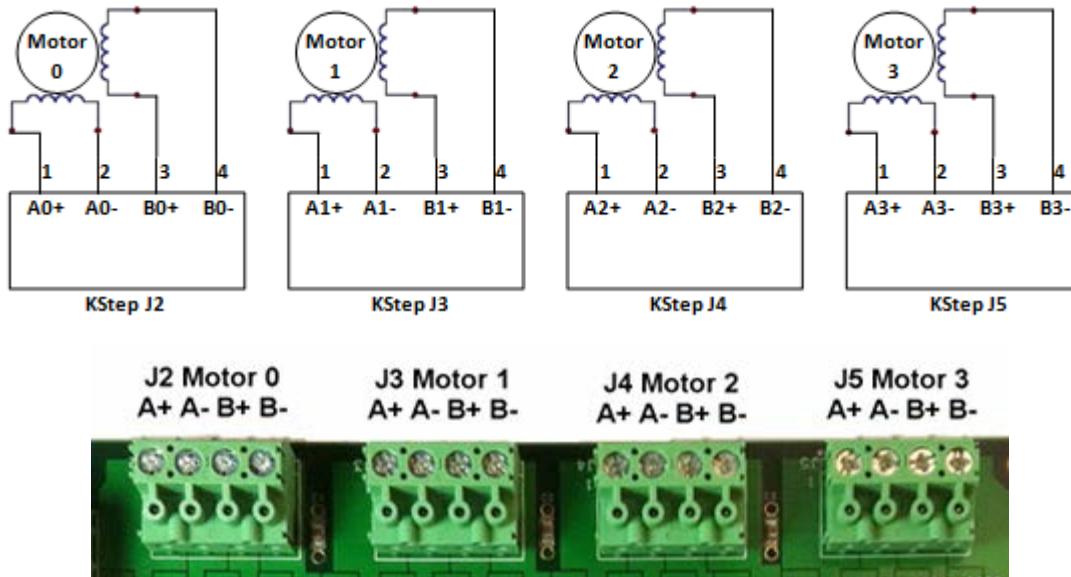

Stepper motors come in a variety of wiring configurations from 4 to 8 wires. KSTEP only needs 4 of these to drive a stepper since KSTEP does not require the center tap wires. KSTEP requires only the full bridge coils to drive the stepper and you can ignore center tap wires if your motor has them.

For 8-wire steppers, you have a choice about how to wire them, in series or in parallel and would need to choose the power supply to fit the wiring method.

There are many resources on the web that describes Stepper motor wiring so we will not address the specifics here, but essentially you need only to wire in the coils across the "+" and "-" of the motor power output of KSTEP.

**Warning:** you can damage KSTEP if you wire the motors incorrectly. Make sure to measure the resistance between coils and that you have identified your coils properly before wiring into KSTEP. It is vitally important that each coil is wired into KSTEP properly.

Motors can be wired into connectors J2 through J5 on KSTEP according to the following diagram:

In addition, take note of the following default mapping as it is useful to know for the next steps (this mapping can be altered in software):

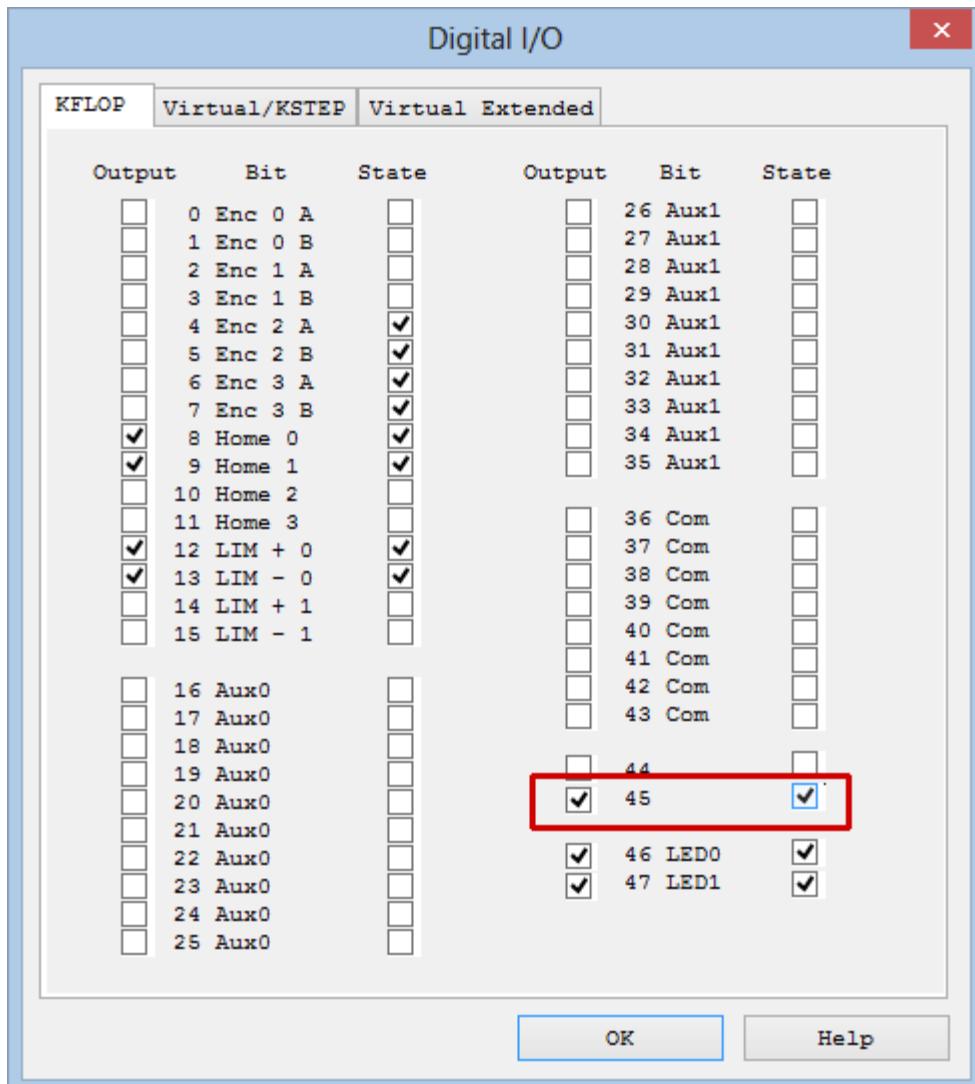

1. Axis Channel #0: Output Channel = 8 -> Motor Wiring J2
2. Axis Channel #1: Output Channel = 9 -> Motor Wiring J3
3. Axis Channel #2: Output Channel = 10 -> Motor Wiring J4
4. Axis Channel #3: Output Channel = 11 -> Motor Wiring J5

### 3. Driving Your Steppers

#### 3A. Enabling Output

Once you have the voltage clamping, current limits and power supply set and wired, you are ready to begin moving your motors.

To do this, while the KSTEP LED D1 MOT PWR is illuminated, open KMotion.exe, select the Digital IO Screen, Set IO bit 45 as Output (enable the checkbox to the left of bit 45), Set IO 45 State to On (enable the checkbox to the right of bit 45). Verify that the KSTEP D3 ENABLE LED illuminates and that your motors hold position against a torque - in other words, you cannot move the motor shaft with your fingers. **In this state, the motors will become warm and may become too hot to touch.**

As a side note, this action can also be performed by entering the following commands in a C program or sending the commands using the Console screen:

```
SetBitDirection(45,1); //This sets the Enable Signal as Output
SetBit(45); //This Enables the amplifiers
```

Or by an external signal wired to KSTEP's J6 terminal.

### 3B. Setting Axis/Channel Parameters and Running an Initialization C Program (Init)

The goal in this section is to set the parameters that will ultimately go into the Init program. To do this, you will use two screens in KMotion: "Config & Flash" and "Step Response." If you plan to use an encoder for Closed-Loop Stepper Control, you would also use the "IIR Filters" screen as well, but it is not used for open-loop stepper control as described in this tutorial. You can view an explanation of how parameters are passed to/from KFLOP, loaded, saved and copied to C Programs here:

<http://dynamotion.com/Help/FlashHelp/Parameters/index.html>.

1. In KMotion, Open the "Config & Flash" Screen and select the "Channel" at the top of the screen for the axis you plan to use (0-3).
2. Since it is best to start with a known default, click on "Load Channel" and choose the corresponding "KStepAxis#.mot" file where # matches the chosen Channel. This will load the last saved settings in that file, which are set to default values that should work for a majority of stepper motors. In addition, loading this file puts the Channel into "Step Dir" Axis output mode, which is required for KSTEP.
3. After loading the Channel, open the "Step Response Screen" screen.
4. Notice at the top that the Channel number matches the Channel number on the Configuration screen. Note: changing the Channel on either the Configuration or the Step Response screen will change the Channel in the other screen.
5. The purpose of the Step Response screen in this tutorial is simply to help you set the Velocity, Acceleration and Jerk values to achieve smooth motor performance. These values are on the Step Response screen under "motion profile" labeled V, A and J, respectively.
6. Click on the 'Move' button. If Channel "0" is chosen, the motor wired to the J2 terminal should move a few degrees one direction and then back to the original position and, after a few seconds, a plot will appear in the Step Response Screen showing the Commanded Step movement. You can increase the step time (up to a maximum of 3.5 seconds) and size in this screen to get a larger movement.
7. Now you can change the V, A, and J values until you are satisfied that the motor is moving smoothly - typically keeping A to be an order of magnitude or more than V, and J to be an order of magnitude more than A. If the motor stalls, seems jerky or misses steps, you can decrease the parameters until motion is smooth. In fact, it is recommended that you increase the parameters until the motor stalls, then decrease the parameters by 30-50%. Note: motors under load will perform differently so you may need to revisit this step once your motors are carrying weight. In that case, take precautions to ensure the system is not damaged if the motor experiences a stall. Click [here for a discussion on choosing values](#) for the Velocity, Acceleration and Jerk parameters.

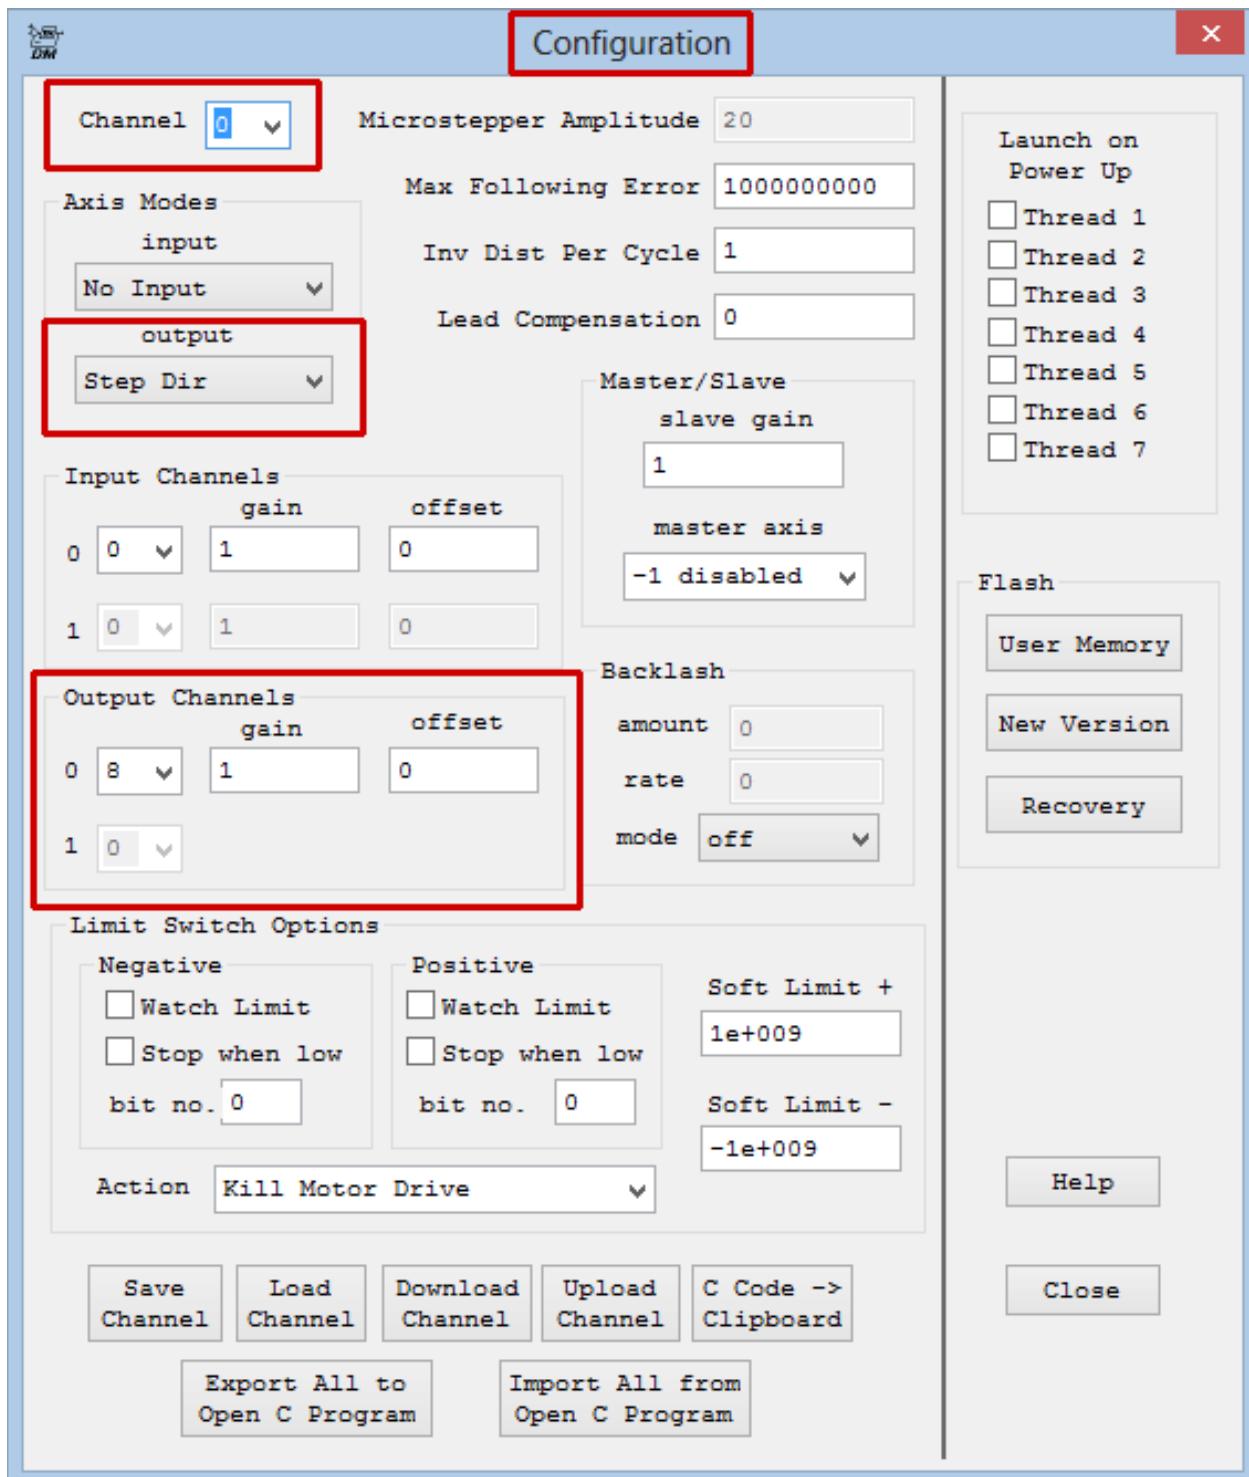

The V, A, and J parameters are in terms of microsteps since KSTEP performs all movements using microstepping, which is 16 microsteps for every step. Therefore a Velocity value of 4,000 means 4,000 microsteps per second. You can relate this to your motor velocity by this

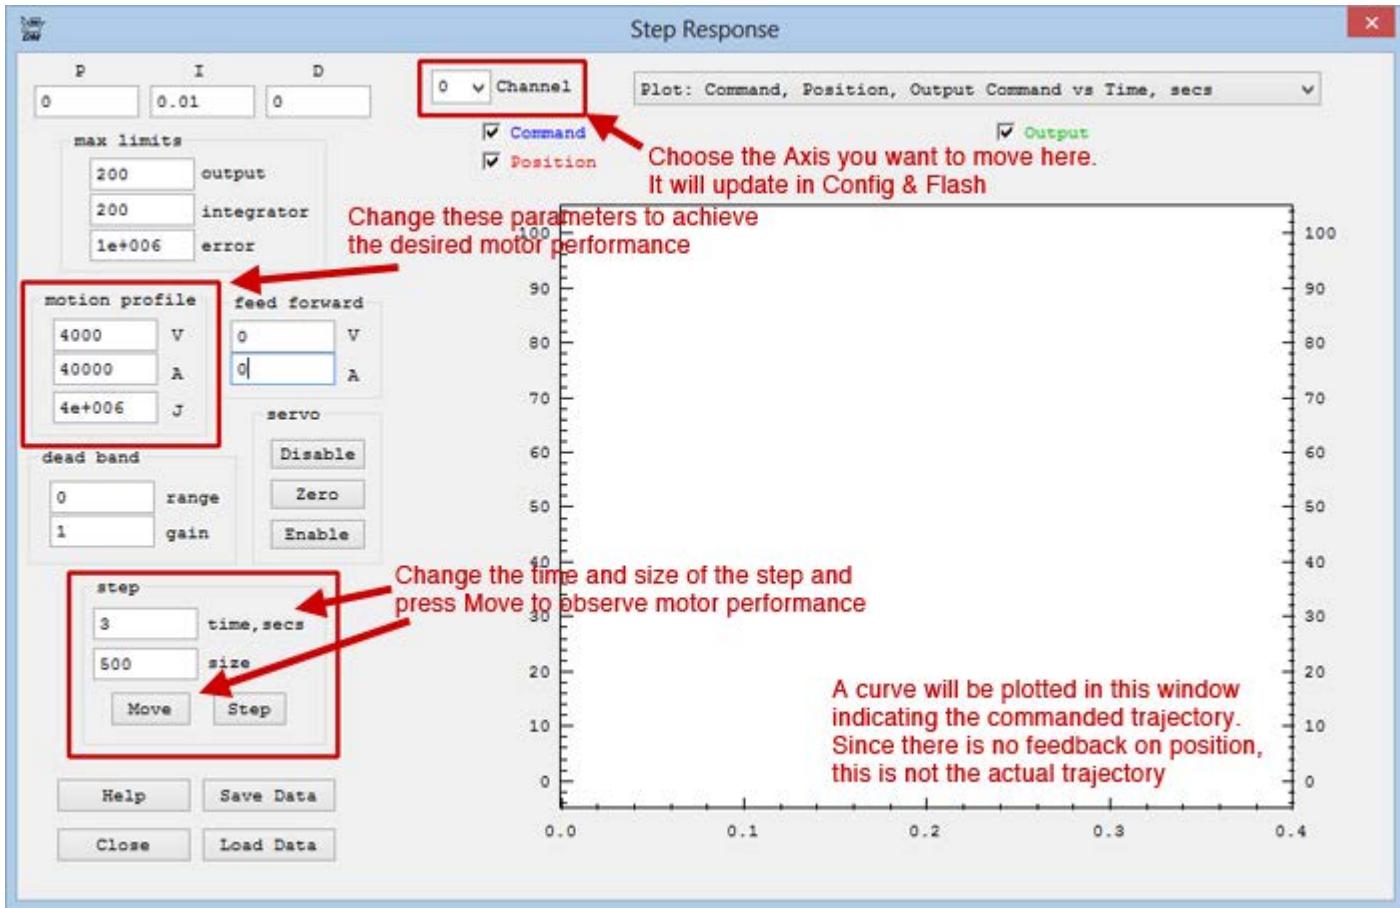

equation:

$$\text{Motor RPM} = 60 * V / (16 * \text{Step/Rev})$$

where V is the Velocity value on the Step Response screen and Step/Rev is the steps per revolution specification for your motor. For a motor with 200 steps/rev, a value of 4,000 for V equates to 75 RPM. Take note of the direction your motor spins and if you want it to spin in the opposite direction you can change the 'gain' value in the Configuration window to '-1'.

8. As the parameters are changed, they are automatically available to the Configuration window so they may be saved, downloaded to KFLOP, copied to the clipboard or exported to an open C program. Furthermore, the parameters for each axis are persistent in that you can select a new Channel and the parameters for the previous Channel will not be lost unless the KMotion program is closed. Because of this, when you copy to the clipboard or export to an open C program, parameters for all axes are copied or exported to the C program (as long as the axis exists in the C program as shown below).

Once the parameters are set, you can save them to a file, export them to a C program or download them to KFLOP. To do this:

- Save to a file:** On the Config & Flash screen, click the Save Channel button and choose a file location and click Save. You can open this file later to reload those parameters.
- Download to KFLOP:** On the Config & Flash screen, click the Download Channel button. This will load KFLOP with the axis parameters.
- Copy to a C Program:** For this you must have a C Program open with the initialization parameters within `int main()`. An example C Program is located in the `\KMotionXXX\C Programs\KStep` folder and a good program to choose is the `InitKStep3Axis.c`, which has parameters for, and enables, 3 axes. Then simply click the 'Export All to Open C Program' and all available channels will be merged into the open C program if channel assignments are present there. This would then become an "Init" file.
- Copy to Clipboard:** This button simply copies the parameters to Window's Clipboard so you may paste into any other text window that you wish.

Here are the parameters for a single axis:

```
ch0->InputMode=NO_INPUT_MODE;  
ch0->OutputMode=STEP_DIR_MODE;  
ch0->Vel=115000;  
ch0->Accel=50000;  
ch0->Jerk=100000;  
ch0->P=0;  
ch0->I=0.01;  
ch0->D=0;  
ch0->FFAccel=0;  
ch0->FFVel=0;  
ch0->MaxI=200;  
ch0->MaxErr=1e+006;  
ch0->MaxOutput=200;  
ch0->DeadBandGain=1;  
ch0->DeadBandRange=0;  
ch0->InputChan0=0;  
ch0->InputChan1=0;  
ch0->OutputChan0=8;  
ch0->OutputChan1=0;  
ch0->MasterAxis=-1;  
ch0->LimitSwitchOptions=0x100;  
ch0->LimitSwitchNegBit=0;  
ch0->LimitSwitchPosBit=0;  
ch0->SoftLimitPos=1e+030;
```

```
ch0->SoftLimitNeg=-1e+030;  
  
ch0->InputGain0=1;  
  
ch0->InputGain1=1;  
  
ch0->InputOffset0=0;  
  
ch0->InputOffset1=0;  
  
ch0->OutputGain=1;  
  
ch0->OutputOffset=0;  
  
ch0->SlaveGain=1;  
  
ch0->BacklashMode=BACKLASH_OFF;  
  
ch0->BacklashAmount=320;  
  
ch0->BacklashRate=320;  
  
ch0->invDistPerCycle=1;  
  
ch0->Lead=0;  
  
ch0->MaxFollowingError=1000000000;  
  
ch0->StepperAmplitude=20;  
  
  
ch0->iir[0].B0=1;  
  
ch0->iir[0].B1=0;  
  
ch0->iir[0].B2=0;  
  
ch0->iir[0].A1=0;  
  
ch0->iir[0].A2=0;  
  
  
ch0->iir[1].B0=1;  
  
ch0->iir[1].B1=0;  
  
ch0->iir[1].B2=0;  
  
ch0->iir[1].A1=0;  
  
ch0->iir[1].A2=0;
```

```
ch0->iir[2].B0=0.000769;  
ch0->iir[2].B1=0.001538;  
ch0->iir[2].B2=0.000769;  
ch0->iir[2].A1=1.92076;  
ch0->iir[2].A2=-0.923833;
```

Notice that the "ch0->" indicates it is setting parameters for Axis #0. Each axis will have all of these parameters and these are what are exported to the C program or copied to the clipboard when those options are selected in the Configuration screen.

Below is the example that shows 3 Axes being configured, enabled, and referenced into a coordinate system. This constitutes a full Init file to initialize a 3-axis system as discussed in the next section:

```
#include "KMotionDef.h"  
  
// Defines axis 0, 1, 2 as simple step dir outputs  
// enables them  
// sets them as an xyz coordinate system for GCode  
  
int main()  
{  
    ch0->InputMode=ENCODER_MODE;  
    ch0->OutputMode=STEP_DIR_MODE;  
    ch0->Vel=40000.000000;  
    ch0->Accel=400000.000000;  
    ch0->Jerk=4000000.000000;  
    ch0->P=0.000000;  
    ch0->I=0.010000;
```

```
ch0->D=0.000000;
ch0->FFAccel=0.000000;
ch0->FFVel=0.000000;
ch0->MaxI=200.000000;
ch0->MaxErr=1000000.000000;
ch0->MaxOutput=200.000000;
ch0->DeadBandGain=1.000000;
ch0->DeadBandRange=0.000000;
ch0->InputChan0=0;
ch0->InputChan1=0;
ch0->OutputChan0=0;
ch0->OutputChan1=0;
ch0->LimitSwitchOptions=0x0;
ch0->InputGain0=1.000000;
ch0->InputGain1=1.000000;
ch0->InputOffset0=0.000000;
ch0->InputOffset1=0.000000;
ch0->invDistPerCycle=1.000000;
ch0->Lead=0.000000;
ch0->MaxFollowingError=100000000.000000;
ch0->StepperAmplitude=20.000000;

ch0->iir[0].B0=1.000000;
ch0->iir[0].B1=0.000000;
ch0->iir[0].B2=0.000000;
ch0->iir[0].A1=0.000000;
ch0->iir[0].A2=0.000000;
```

```
ch0->iir[1].B0=1.000000;
ch0->iir[1].B1=0.000000;
ch0->iir[1].B2=0.000000;
ch0->iir[1].A1=0.000000;
ch0->iir[1].A2=0.000000;

ch0->iir[2].B0=0.000769;
ch0->iir[2].B1=0.001538;
ch0->iir[2].B2=0.000769;
ch0->iir[2].A1=1.920810;
ch0->iir[2].A2=-0.923885;
EnableAxisDest(0,0);

ch1->InputMode=ENCODER_MODE;
ch1->OutputMode=STEP_DIR_MODE;
ch1->Vel=40000.000000;
ch1->Accel=400000.000000;
ch1->Jerk=4000000.000000;
ch1->P=0.000000;

ch1->iir[1].B2=0.000000;  
ch1->iir[1].A1=0.000000;  
ch1->iir[1].A2=0.000000;
```

```
ch1->iir[2].B0=0.000769;
ch1->iir[2].B1=0.001538;
ch1->iir[2].B2=0.000769;
ch1->iir[2].A1=1.920810;
ch1->iir[2].A2=-0.923885;
EnableAxisDest(1,0);

ch2->InputMode=ENCODER_MODE;
ch2->OutputMode=STEP_DIR_MODE;
ch2->Vel=40000.000000;
ch2->Accel=400000.000000;
ch2->Jerk=4000000.000000;
ch2->P=0.000000;
ch2->I=0.010000;
ch2->D=0.000000;
ch2->FFAccel=0.000000;
ch2->FFVel=0.000000;
ch2->MaxI=200.000000;
ch2->MaxErr=1000000.000000;
ch2->MaxOutput=200.000000;
ch2->DeadBandGain=1.000000;
ch2->DeadBandRange=0.000000;
ch2->InputChan0=2;
ch2->InputChan1=0;
ch2->OutputChan0=2;
ch2->OutputChan1=0;
```

```
ch2->LimitSwitchOptions=0x0;  
ch2->InputGain0=1.000000;  
ch2->InputGain1=1.000000;  
ch2->InputOffset0=0.000000;  
ch2->InputOffset1=0.000000;  
ch2->invDistPerCycle=1.000000;  
ch2->Lead=0.000000;  
ch2->MaxFollowingError=1000000000.000000;  
ch2->StepperAmplitude=20.000000;  
  
ch2->iir[0].B0=1.000000;  
ch2->iir[0].B1=0.000000;  
ch2->iir[0].B2=0.000000;  
ch2->iir[0].A1=0.000000;  
ch2->iir[0].A2=0.000000;  
  
ch2->iir[1].B0=1.000000;  
ch2->iir[1].B1=0.000000;  
ch2->iir[1].B2=0.000000;  
ch2->iir[1].A1=0.000000;  
ch2->iir[1].A2=0.000000;  
  
ch2->iir[2].B0=0.000769;  
ch2->iir[2].B1=0.001538;  
ch2->iir[2].B2=0.000769;  
ch2->iir[2].A1=1.920810;  
ch2->iir[2].A2=-0.923885;
```

```

EnableAxisDest(2,0);

DefineCoordSystem(0,1,2,-1);

return 0;

}

```

You can find more information on how to quickly import or export settings between the KMotion Screens and a C Program [here](#).

### 3C. The Four Requirements for an Init C Program

At this point, you are ready to begin writing a C program to move your motors or simply use it as an Initialization file that allows KMotionCNC to control them. An initialization C program, which is also referred to simply as an Init file, will have four operations (all of which the InitKStep3Axis.c and InitKStep4Axis.c programs already have):

1. The following commands:

```

KStepPresent=True; //which tells KFLOP that KSTEP is connected
FPGA(KAN_TRIG_REG)=4; //Mux PWM0 to JP7 Pin5 IO 44 for KSTEP
FPGA(STEP_PULSE_LENGTH_ADD) = 63 + 0x80; //which sets polarity and pulse
length to 4us

```

2. Axis settings such as the velocity, acceleration and jerk parameters as described in the previous section along with the following command **for each axis**:

```
EnableAxisDest(#,0); //where # is the axis/channel number
```

3. Commands to enable all axes:

```

SetBitDirection(45,1); //This sets the Enable Signal as Output
SetBit(45); //This Enables the amplifiers

```

4. And then a command that defines which axes are in the coordinate system:

```
DefineCoordSystem(0,1,2,-1);
```

5. This command defines a coordinate system with 3 axes: 0, 1, 2 and the 4th axis is disabled by entering a '-1', otherwise a '3' would be used to include the 4th axis.

You can add more C code into this initialization file to control your system, or use KMotionCNC's program to run G-Code.

Since adding C code is more involved, that will be handled in a different tutorial, but here is an example of a simple infinite loop to move one motor that can be added into an init file:

```
for(;;) //loop forever
{
    MoveRelAtVel(0,500,100); //relative move Axis 0 for 500 steps at 100
    //steps/second
    while (!CheckDone(0)) ; //ensure the move of Axis 0 is complete before
    //moving on
    MoveRelAtVel(0,-500,100); //relative move Axis 0 for 500 steps in opposite
    // direction at 100 steps/second
    while (!CheckDone(0)) ; //ensure the move of Axis 0 is complete before
    //moving on
} // close loop (loop still loops forever)
```

Then you only need to Save, Compile, Download and Run the program to have KFLOP execute the program. You can do this in steps on the C Program screen or all in one button click with the Save-Compile-Download-Run button on the top. To stop the program, press the "Stop" button on the main KMotion menu.

The next steps cover how to use KMotionCNC for basic movements.

### **3D. Use KMotionCNC to jog your motors**

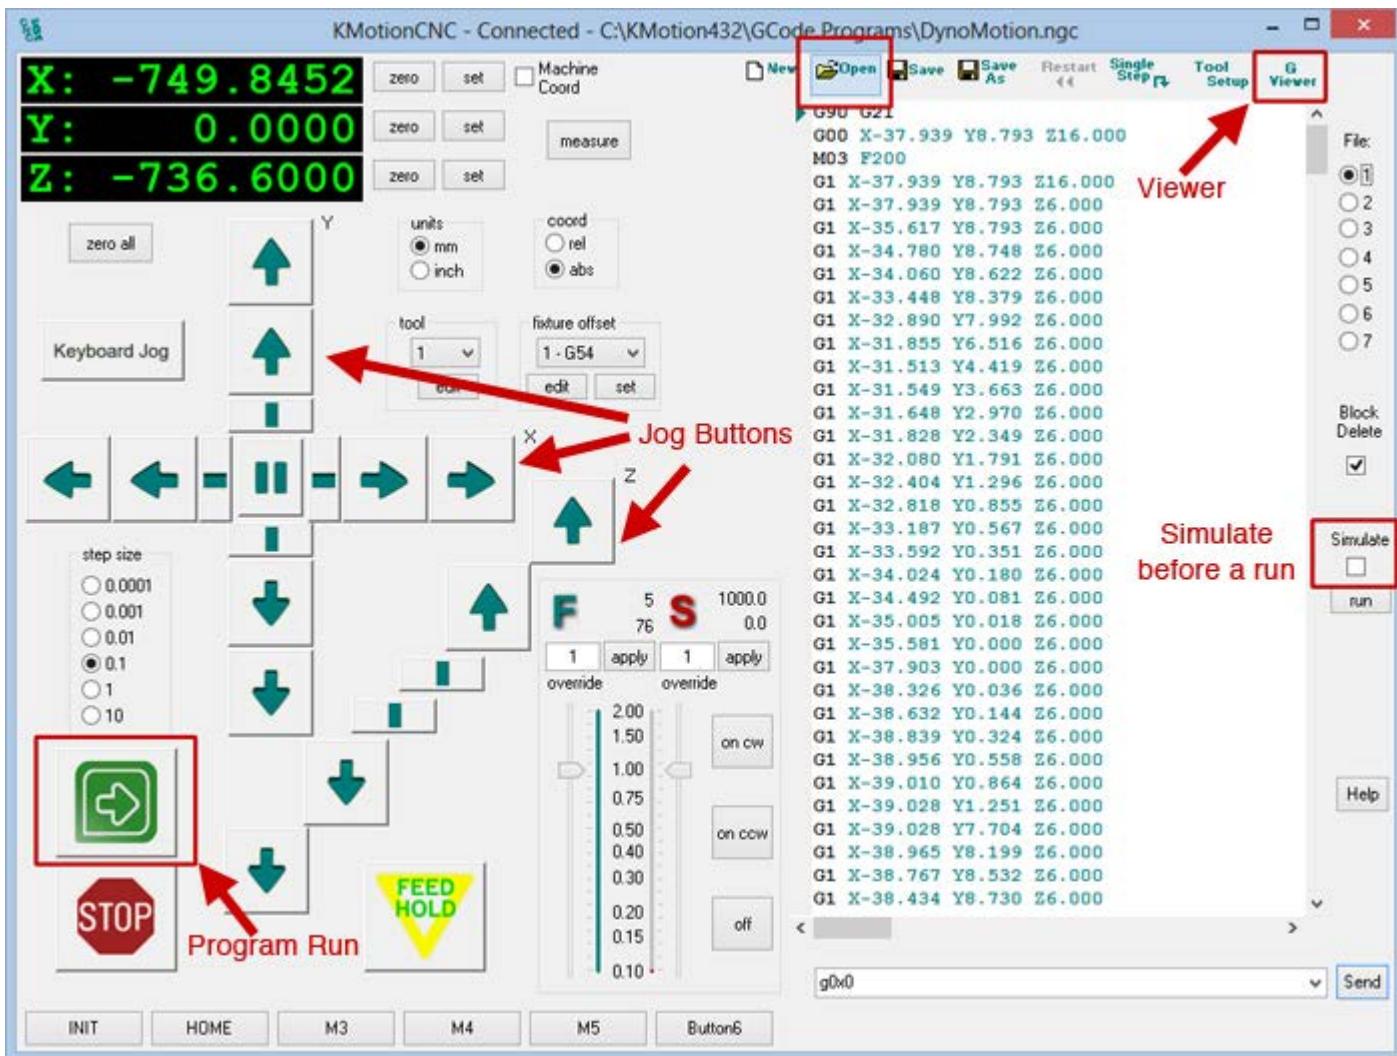

After running an Init file such as InitKStep3Axis.c for initialization, you are ready to move your motors by using KMotionCNC. Try moving the motors by first clicking on the jog buttons (buttons with green arrows at left). If everything is initialized properly the motors should move when the respective jog button is clicked. These jog buttons are mapped to the axes by the "DefineCoordSystem(0,1,2,-1);" command discussed above. In this example, the X-axis is mapped to Axis #0, Y-axis is mapped to Axis #1, Z-axis is mapped to Axis #2 and the A-axis is not used. If pressing the jog buttons move the motors, then you are ready to begin running G-Code. To do this,

within KMotionCNC choose "Open" and choose a G-Code program from the GCode Programs folder. If everything has been initialized correctly, the motors will move when the Start button is pressed to start the G-Code.

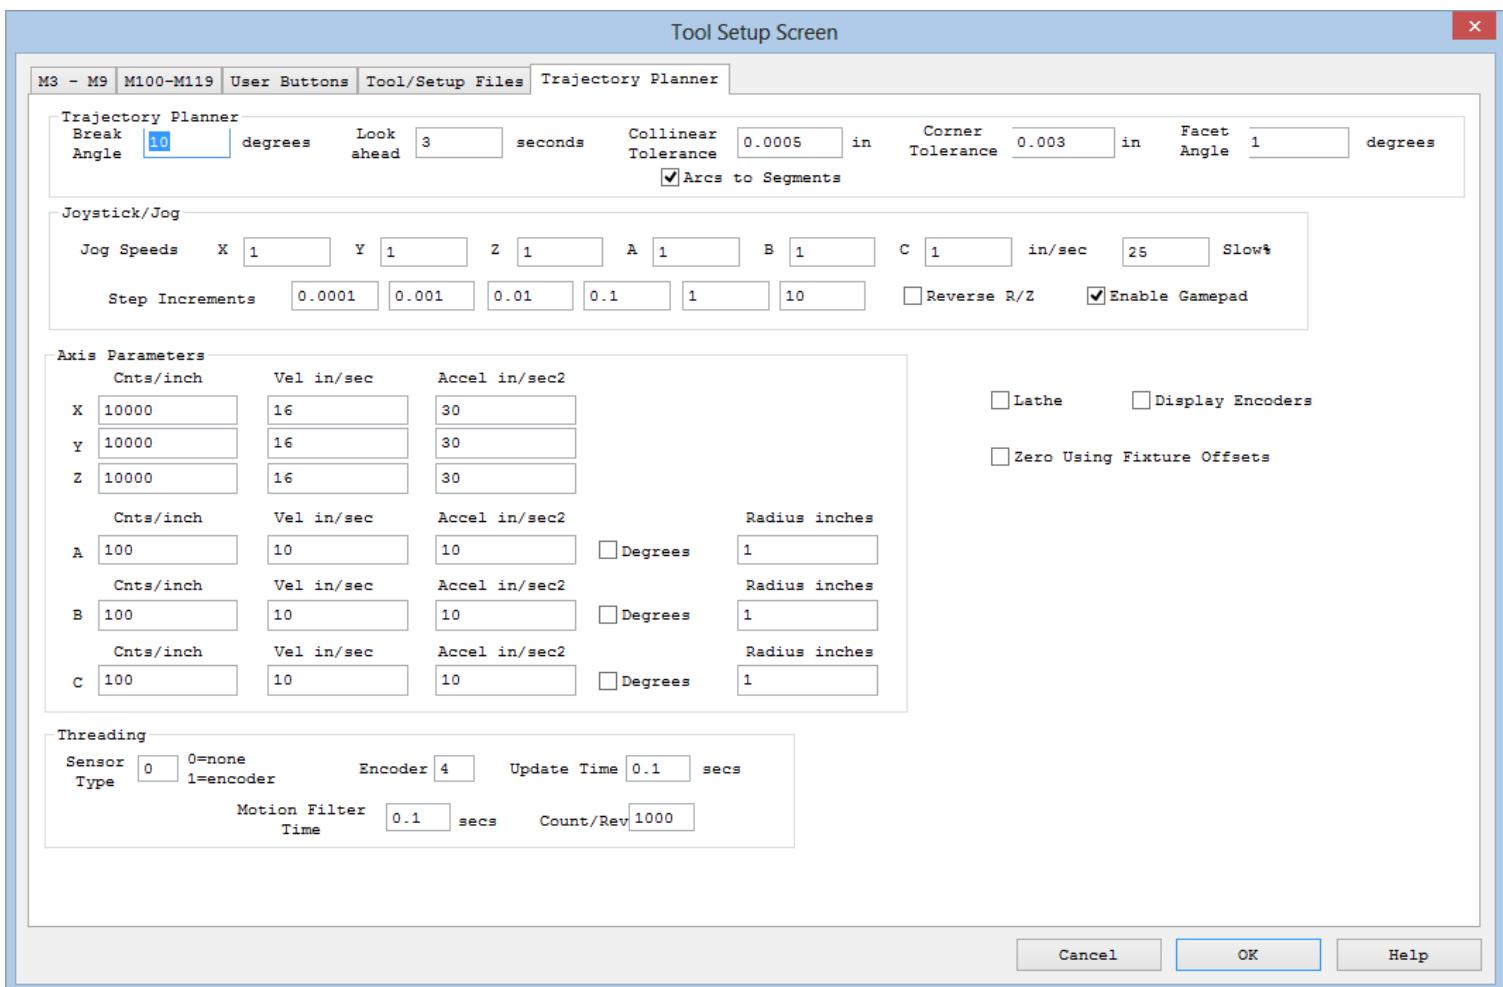

Note: An initialization C program such as the InitKStep3Axis.c must be run before operating with KMotionCNC will work. This initialization C program can be called with the 'Init' button in KMotionCNC once programmed to do so by setting the file location and Thread number for the INIT button within the 'Tool Setup' Screen on the 'User Buttons' tab in KMotionCNC:

The GUI of KMotionCNC can be configured based on how many axes you are using by changing the option for "Main Dialog Face" on the 'Tool/Setup Files' tab within the 'Tool Setup' screen. The screenshot below is for a 3-axis setup as you can tell from the display of only X, Y, and Z coordinates.

Note that the motors will not yet be moving accurately until the full parameters are set within KMotionCNC. To do this, you will set the Counts per inch (Cnts/inch) for each axis on the Trajectory Planner tab within the Tool Setup screen of KMotionCNC. You should also set the axis velocities and accelerations, and jog velocities and accelerations for your system on this tab.

You can measure the distance each axis moves for a given number of steps and then use this Cnts/inch value as a conversion factor so KMotionCNC knows how many steps to move for a given distance.

For greater accuracy, you can create a [Geocorrection File](#).

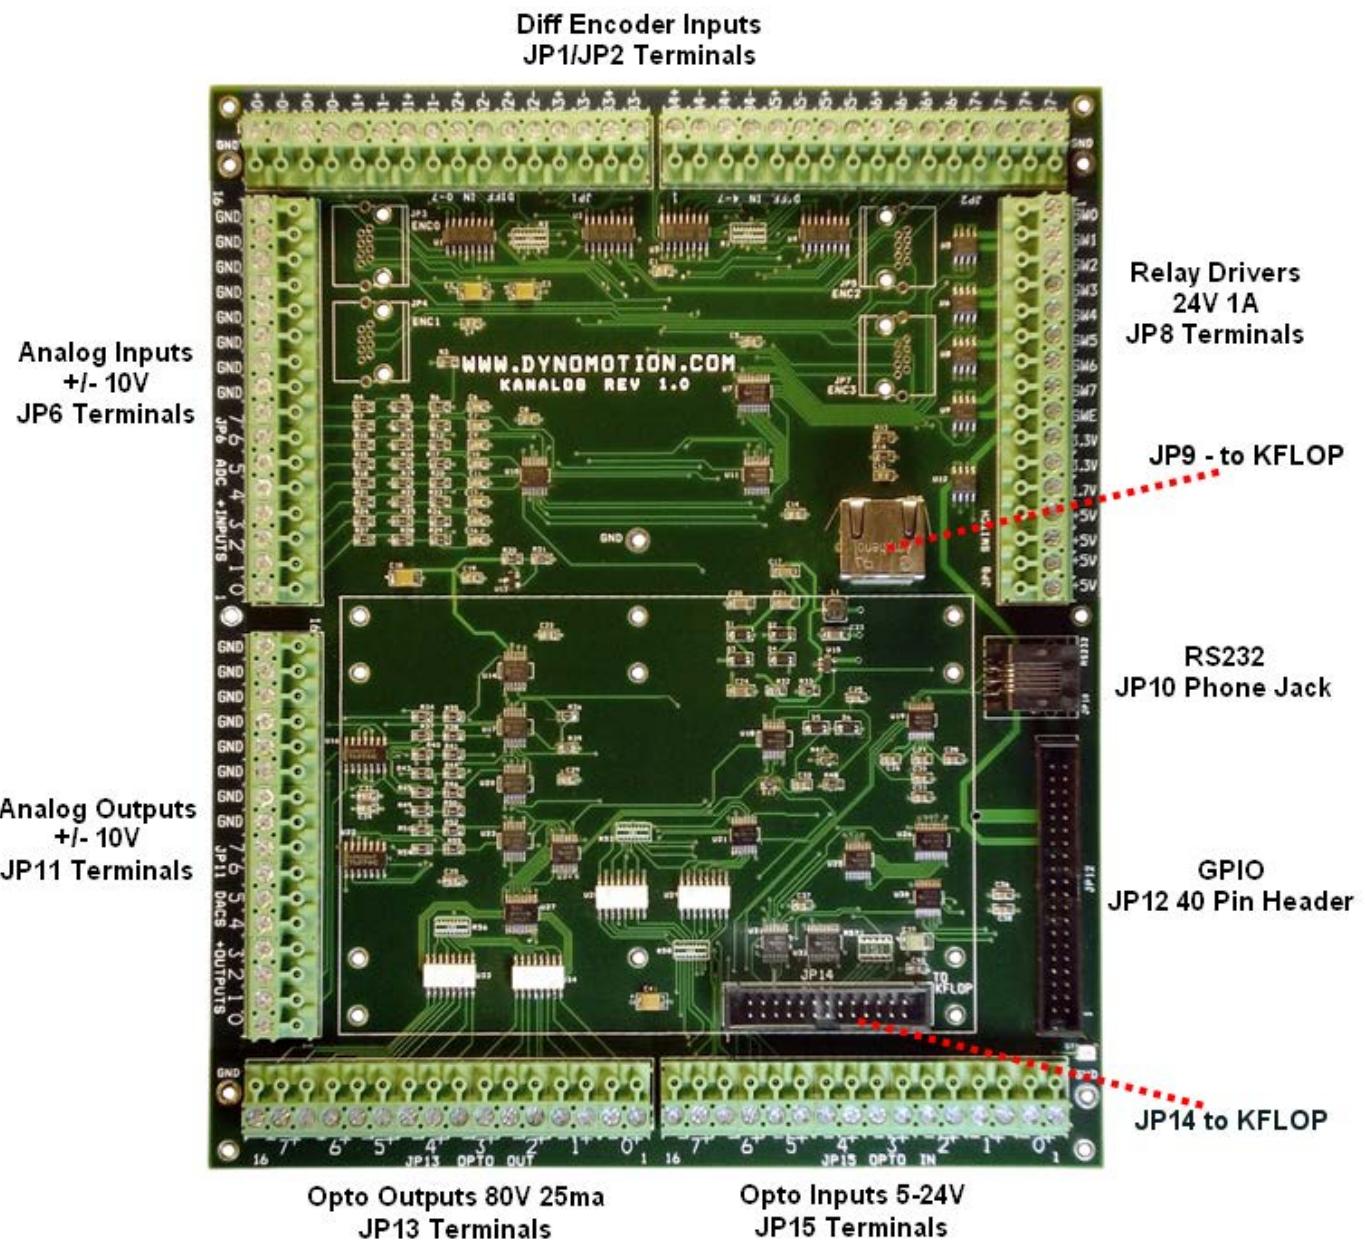

For a detailed discussion on Step and Direction Outputs, [see this page](#).

Once you understand everything in this tutorial, you will be ready to dive into the details of your KFLOP/KSTEP. See our [manual](#) for more information.

## Kanalog 1.0 Hardware

Function	Parameter	Specification
Analog	DAC Outputs ADC Inputs	(8) +/- 10V @ 10ma, recommended load >2Kohm 12 bit - update rate 11.1KHz all 8 channels (8) +/- 10V 100Kohm input Impedance 12 bit - update rate 11.1KHz all 8 channels
Optos	Opto Isolated Outputs Opto Isolated Inputs	(8) Max differential voltage 80V 25ma (8) 3-24V input, internal 10KOhm series resistor
Differential	Differential Receivers	Input (16) ANSI TIA/EIA-422-B, ANSI TIA/EIA-423-B +/-7V common mode range, 200mv sensitivity Internal 470ohm termination
Relay Drivers	N channel FET Switches	(8) 24V @ 1 Amp max Open Drain switches to ground
Digital I/O	GPIO - LVTTL	(8) Outputs Source/Sink 12ma (8) Inputs LVTTL, 3.3V 1µa max
$\pm 15V$	On-board Generator	DC-DC 2 Watts (70ma each supply)
RS232	Driver/Receiver	EIA/TIA-232-F
Terminal Strips	Screw Terminals	112 Pluggable Screw Terminals (7) x 16 pin 5mm pitch
Watchdog	Charge Pump	DSP communication enables (1) Relay Driver, FET Switch 24V @ 1A
Logic Supply	Voltage Typical Current	+5V ±10% 0.5 A
Environment	Operating Temperature Storage Temperature Humidity	0-40° C 0-40° C 20-90% Relative Humidity, non-condensing
Dimensions	Length Width Height	8.5 inches (216mm) 7.0 inches (178 mm) 0.75inches (19 mm)
Green	RoHS	Compliant

## Kanalog - Connector Pinouts

### JP1/JP2 Differential Inputs

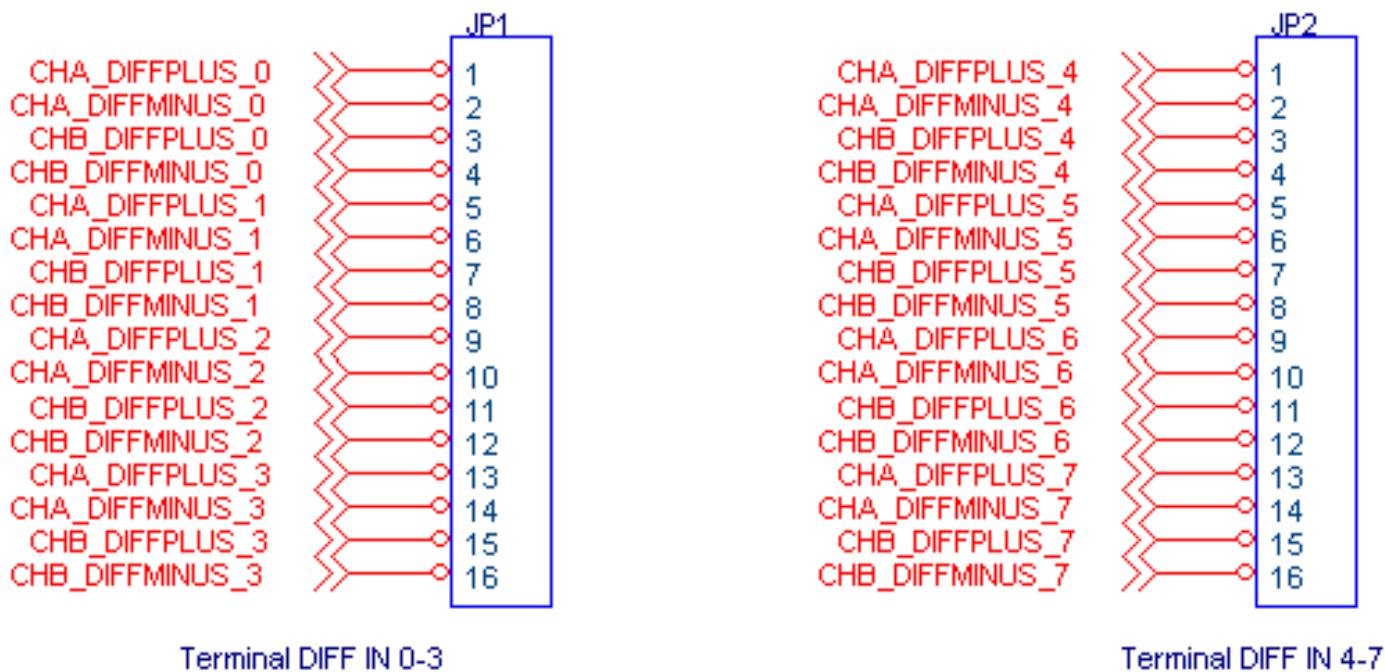

16 Differential Receiver Inputs are provided. Kanalog converts the differential signals to signal ended LVTTL signals and passes them through to existing KFlop I/O pins.

JP1 converts 8 of the signals and connects them to Kflop I/O bits 0-7 (Kflop JP7 Pins 7-14) which are Kflop's 4 encoder A/B input channels.

JP2 converts 8 of the signals and connects them to Kflop I/O bits 36-43 (Kflop JP5 Pins 1-8) which are General Purpose I/O pins.

Typically up to 4 encoder's A/B signals are connected to JP1 and any Z index inputs are connected to JP2

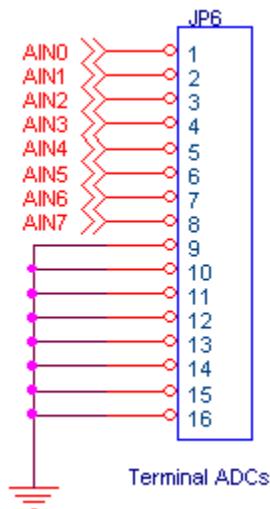

These differential inputs are moderately damped with an internal 470ohm resistor connected across the + to - inputs. If additional termination is required an external resistor may be connected.

### JP6 - Analog Inputs +/- 10V

(8) +/- 10V analog inputs are provided. These are mapped and referenced as ADC inputs 0-7 for Kflop configuration purposes. Input impedance is approximately 100K ohms.

(8) ground terminals are provided. Kanalog contains a single solid ground plane so these grounds may be used as any digital or analog ground connection.

### **JP8 - FET Switch Outputs (relay drivers) - watchdog - power outputs**

(8) 24V @ 1Amp relay FET Switch Outputs are available on Kanalog mapped as Output Bits 152-159. When activated (checked on or with state "1") the FET Switches make a connection to ground. Normally a load, such as a relay coil is connected between some appropriate +supply and a Switch input. Therefore when the Switch makes a connection to ground, the load is energized.

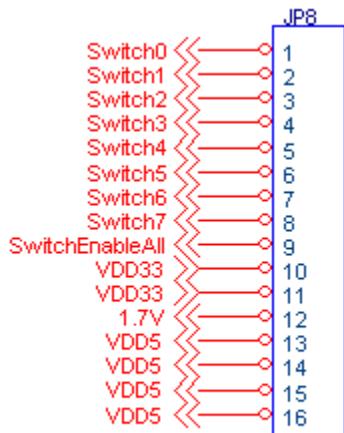

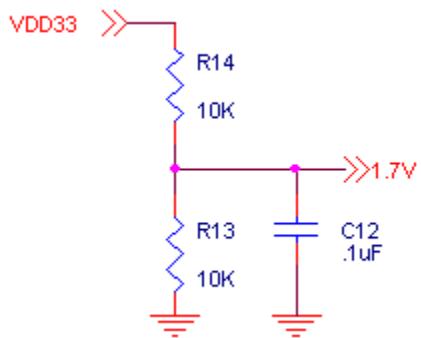

**Caution! Inductive loads MUST have a reverse diode connected in parallel with the load to avoid a high voltage spark when the switch opens. Failure to allow a re-circulating current path on any inductive coil such as a relay, solenoid, or motor is likely to cause permanent damage.**

One Enable or Watchdog FET Switch Output is also available (24V @ 1Amp). This switch conducts after Kflop boots, enables the +/-15V generator, and begins communicating with the board. It is recommended that this switch output is used as one of the conditions to enable main system power for motors and other devices.

(2) +3.3V outputs are available to power low current (<100ma) external circuitry.

One low current 1.7V bias current is available. See circuit below:

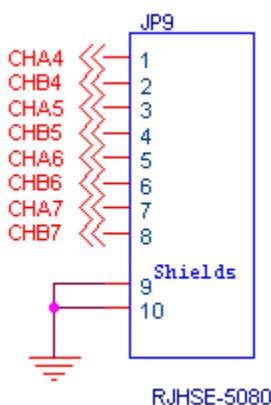

(4) +5V outputs are available to power low current (<100ma) external circuitry such as encoders. Normally +5V is applied to Kflop JR1 (4 pin white Molex connector) and passes through the ribbon connector to Kanalog. However it is also possible to feed +5V into the system via these terminals. If +5V power is fed into both Kflop and Kanalog the exact same +5V supply must be connected to both.

Terminal Relay Drivers/Power

### JP9 - Differential Signals 8-15 to Kflop

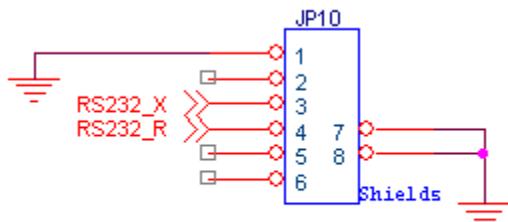

The second (8) of the 16 Differential signals pass through to KFlop through this connector. If only the first 8 differential are used then this connector is not required and the 8 Kflop inputs may be used for some other purpose.

RJHSE-5080

## JP10 - RS232

The JP10 6-pin phone connector provides 3-wire RS232 connectivity. JP10 Pin3 is used for transmit data from Kanalog. JP10 Pin 4 is used for receive data going into Kanalog. Receive data is converted to LVTTL and routed to a Kflop I/O bit #44. Data from LVTTL Kflop I/O bit #45 is passed through the RS232 driver and out the Transmit pin. This phone plug connector is designed to be compatible with [Automation Direct's](#) PLC line using a straight through phone cable.

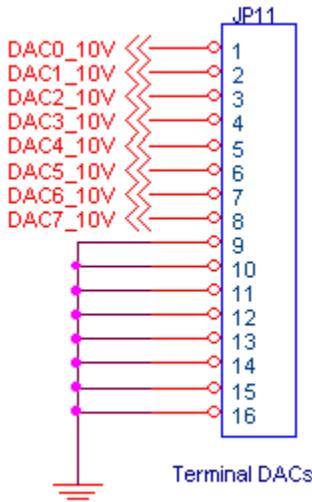

RJ12 TYCO 5555165-1

## JP11 - Analog Outputs +/- 10V

(8) +/- 10V analog outputs are provided. These are mapped and referenced as DAC outputs 0-7 for Kflop configuration purposes. Output impedance is approximately 2K ohms.

(8) ground terminals are provided. Kanalog contains a single solid ground plane so these grounds may be used as any digital or analog ground connection.

## **JP12 - General Purpose Inputs, Outputs, Low level analog in, Supplies**

JP12 is a standard 40 pin IDC header connector.

(8) 3.3V LVTTL Inputs are provided (SDIN0 - SDIN7) mapped as Kanalog Input bits #128-135. Inputs are diode clamped to 3.3V.

**Note: To connect 5V signals a 200ohm external series resistor is required.**

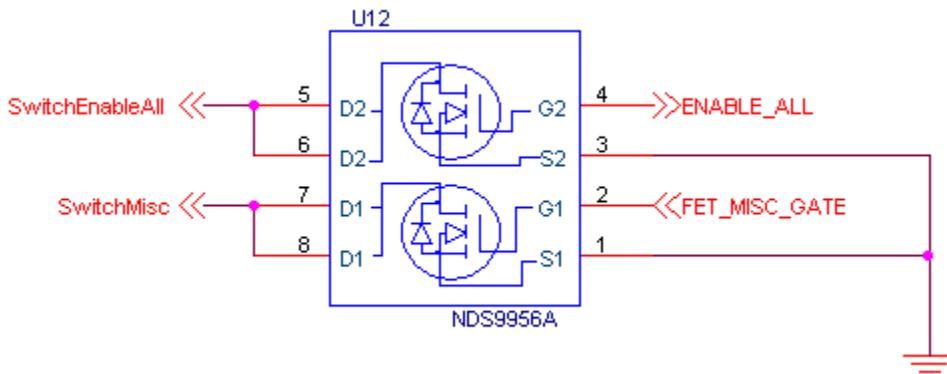

(8) 3.3V LVTTL Outputs are provided (OUT 0 - OUT\_7) mapped as Kanalog Output bits #160-167.

ADC channels 0-3 have internal low voltage inputs exposed as signals IN0-IN3. Instead of driving the normal terminal inputs with a voltage range of +/- 10V. The INx pins may be driven with low voltage (0V - 3V) signals with an input impedance of ~10K ohms. This may allow higher resolution with low voltage signals. Caution should be used as these are low voltage unprotected signal inputs.

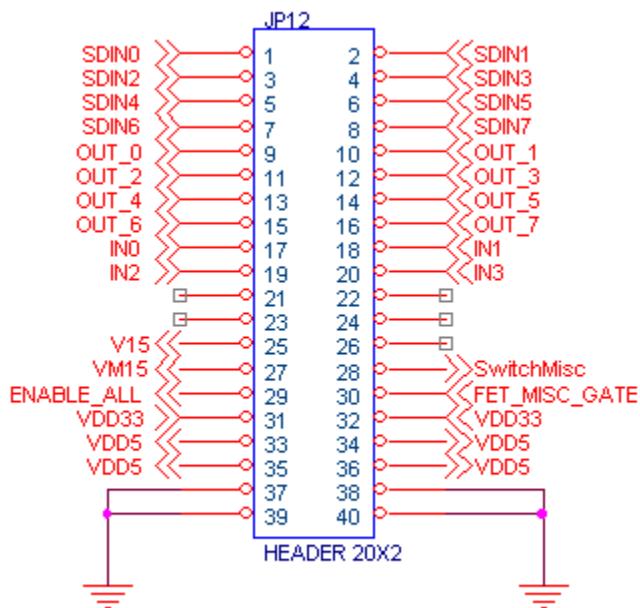

+/- 15V from the internal DC-DC generator is available on pins V15 (+15V) and VM15 (-15V). 70mA is available for external use for each supply.

ENABLE\_ALL is the LVTTL equivalent of the SwitchEnableAll FET output if a logic level is desired instead of the FET SWITCH output.

One additional 24V 1Amp FET switch is available with an exposed gate. Drive signal FET\_MISC\_GATE to 3.3v to turn on the FET (SwitchMisc) output.

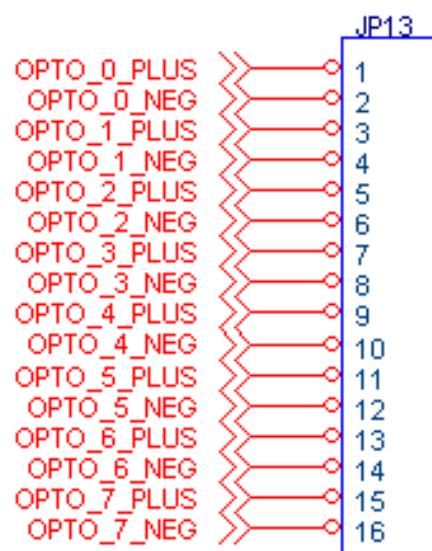

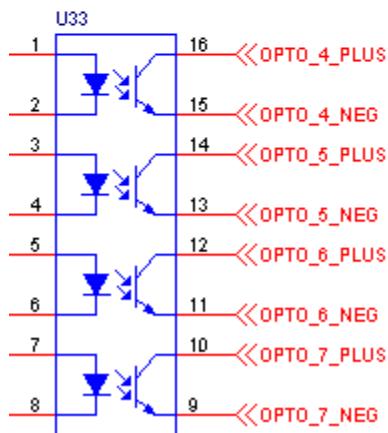

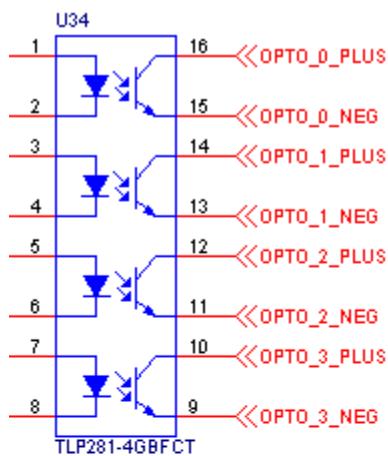

+3.3V and +5V are available on this connector. +3.3V is available as an output only (regulated down from the +5V). +5V is common to all other +5V signals and may be used as input or output.

### JP13 - Opto Outputs

(8) totally isolated and independent optically isolated outputs are provided.

Opto output transistors are rated for a max voltage of 80V and will conduct up to 25ma of current.

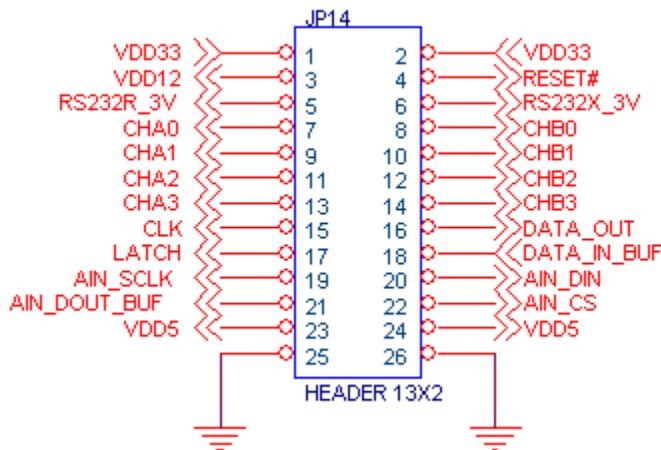

Terminal Opto Out

## **JP14 - Kflop**

This is the main connection between Kflop and Kanalog and should consist of a short 26-pin one-one ribbon cable.

Analog and digital data passes through this cable in serial form. The first 8 differential signals pass to the Kflop in parallel form.

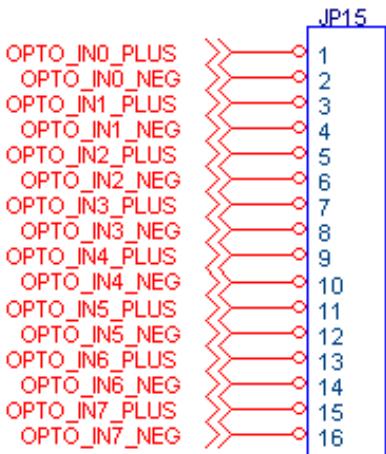

None of these signals should be used by the User.

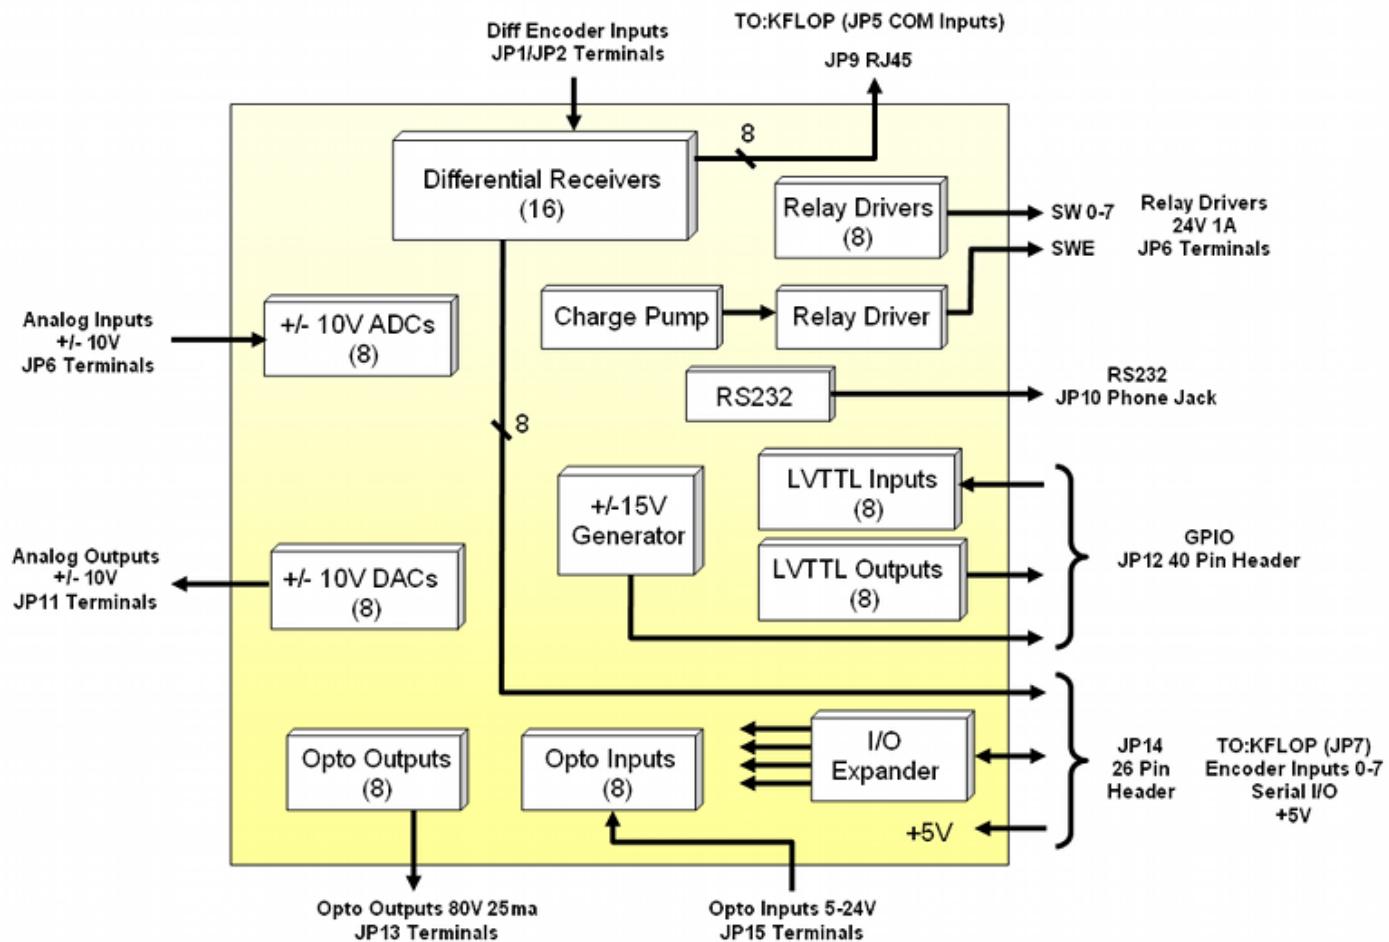

## **JP15 - Opto Inputs**

(8) totally isolated and independent optically isolated inputs are provided.

Input LEDs have a series resistance of 10Kohms and may be driven directly by any voltage from 5-24V. Max drain of 2.4ma when driven with 24V.

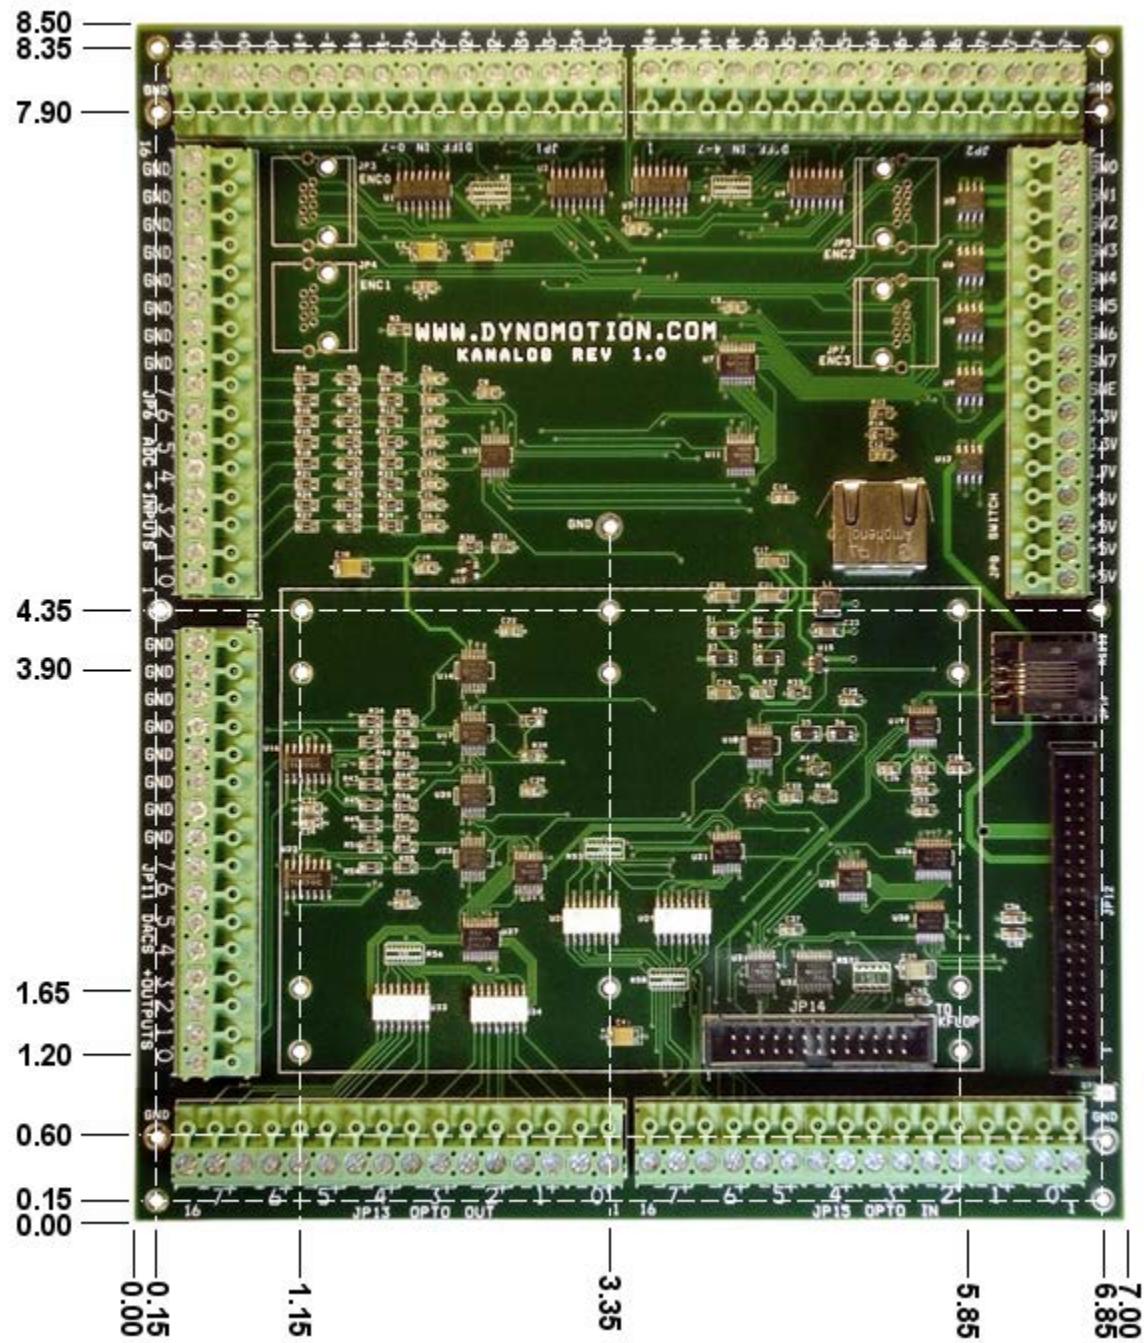

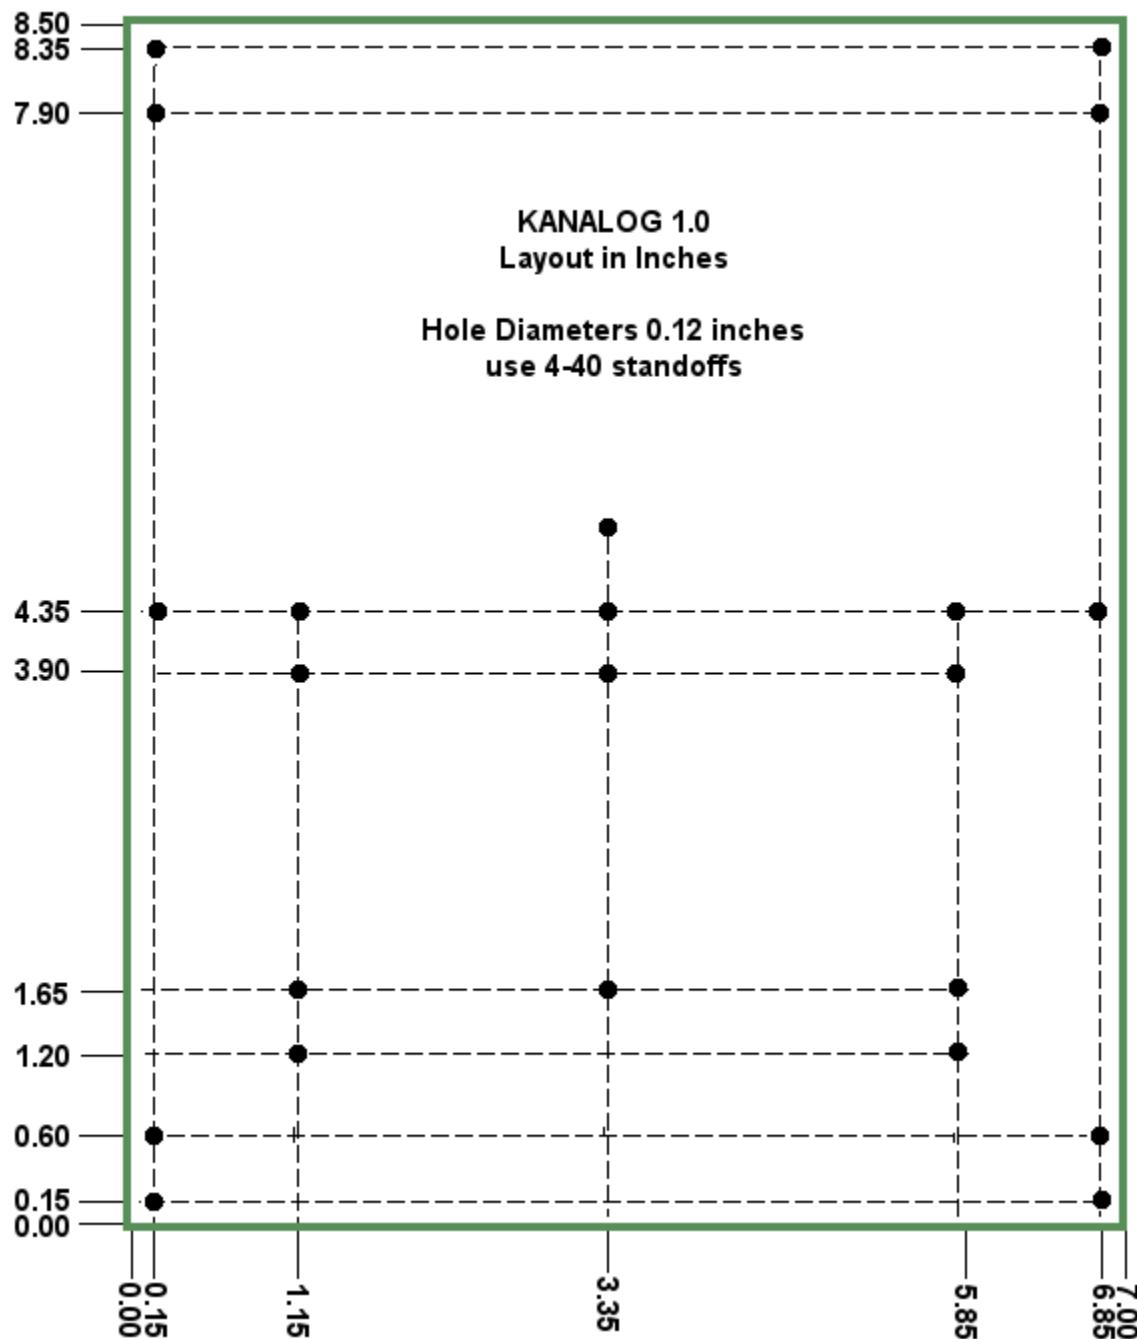

Terminal Opto In

## Kanalog Block Diagram

## Kanalog Board Layout

## Using Kanalog 1.0

Kanalog adds Analog and Digital I/O to Dynomotion's *KFLOP* motion controller.

Kanalog provides 6 types of various I/O which is enough to completely drive many types of machine tools.

Standard +/-10V Analog outputs may be used to drive Analog Motor Drives. The Analog outputs are true 12 bit DACS, *not* filtered PWMs that have slow response and ripple. All (8) Analog inputs and (8) Analog outputs are all updated every Servo Sample time of 90us (11 KHz).

Relay Drivers, Opto Inputs, Opto Outputs, Differential Encoder Inputs, LVTTL inputs and outputs are all included along with 112 screw terminals.

The photo below shows Kanalog with KFlop mounted and two cables that connect the two boards.

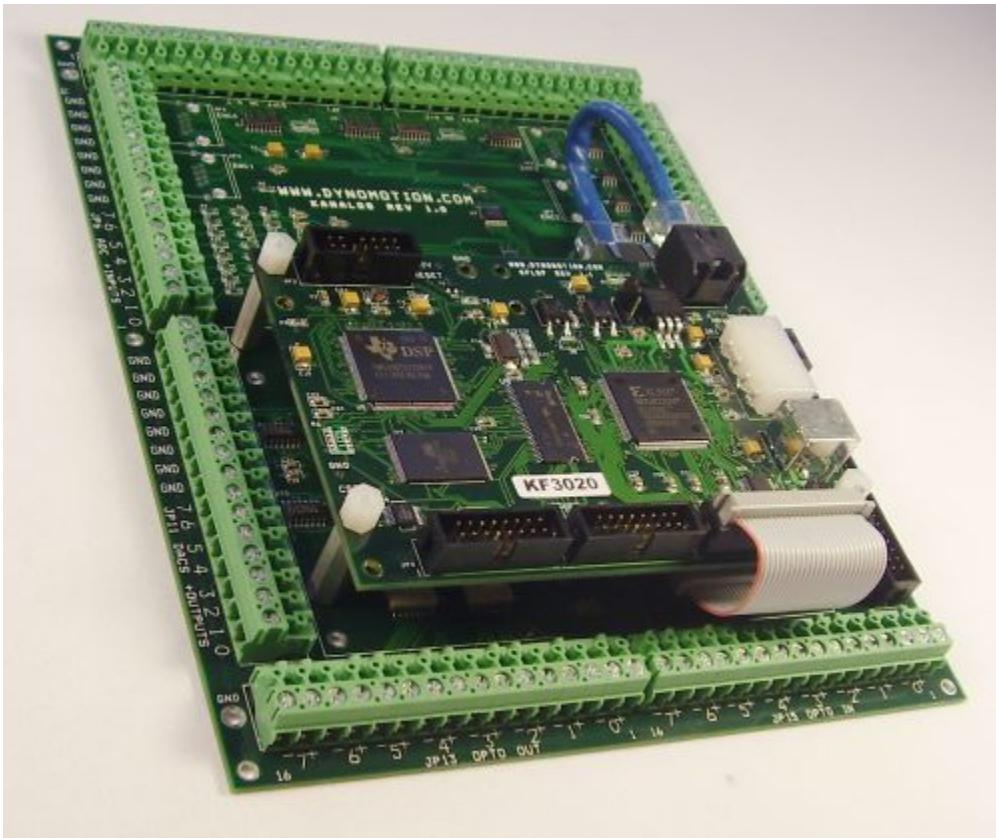

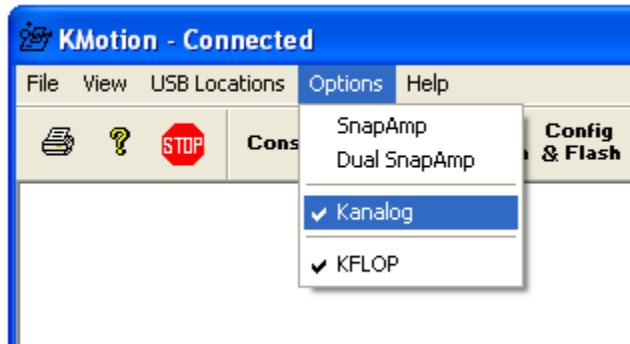

Figure 1 - Kanalog + KFLOP

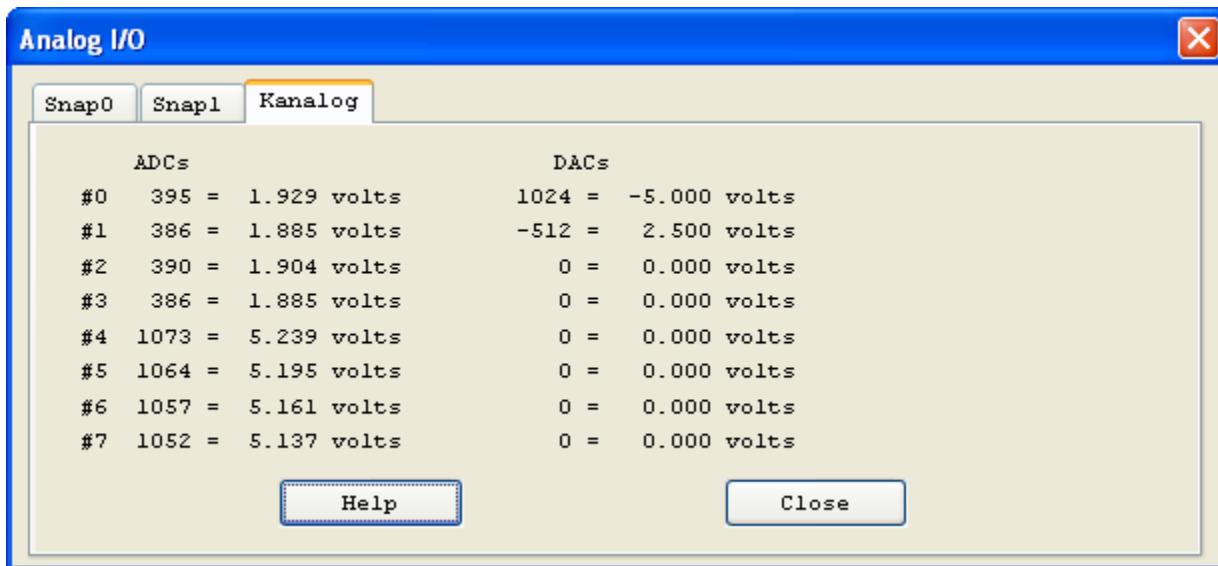

## Setting Options

Set options on the KMotion Executive Program for both Kanalog and the required KFlop.

### Analog Status

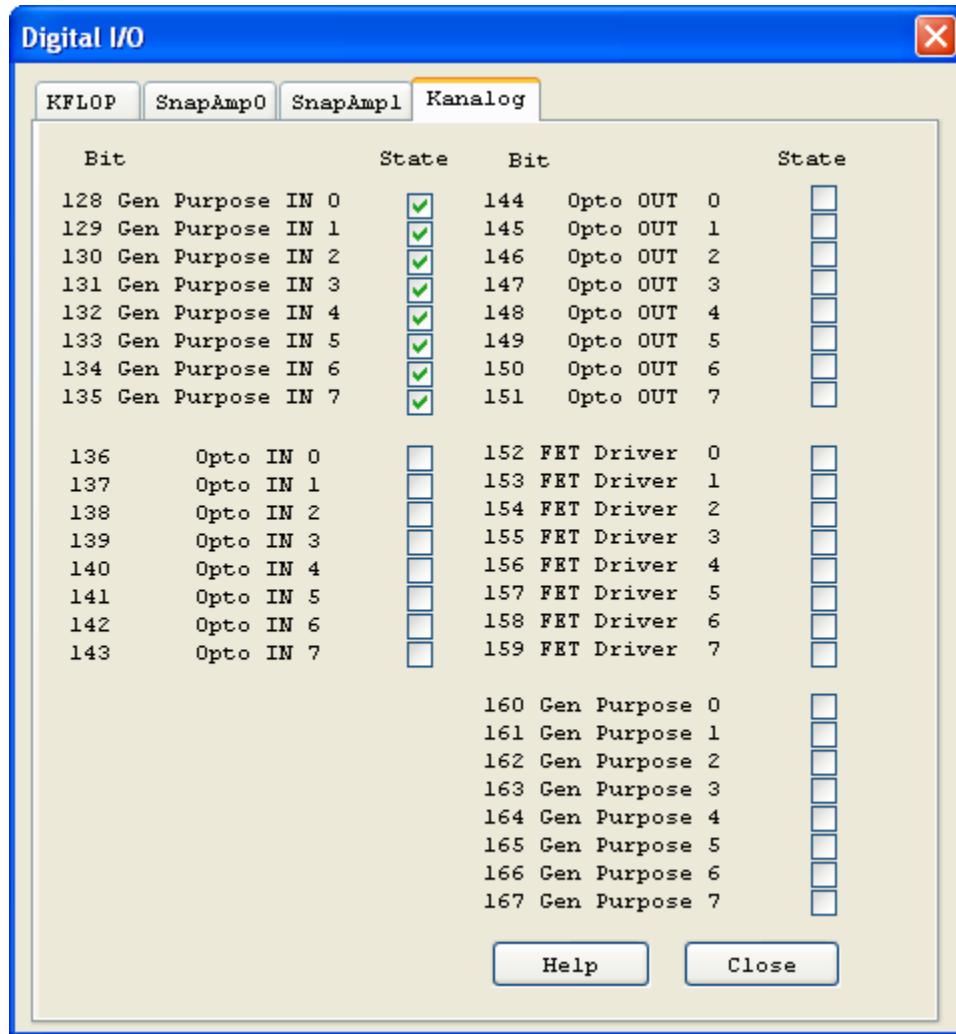

All of the Analog ADC readings and DAC settings can be observed by selecting the Kanalog Tab of the Analog I/O Screen.

### Digital Status

All of the Digital I/O can be observed by selecting the Kanalog Tab of the Digital I/O Screen.

Inputs are all on the left side of the screen and Outputs are on the right. Outputs may be toggled by clicking on the state.

## Example Configuration

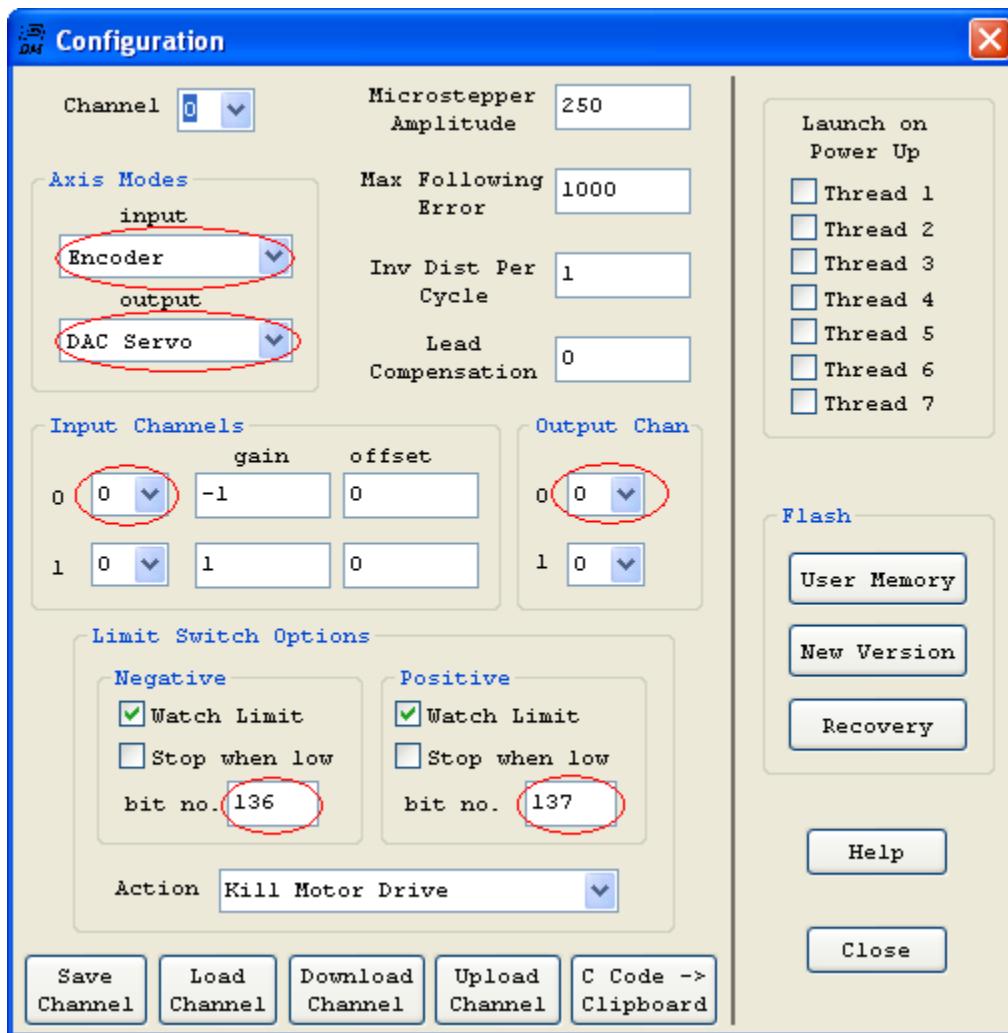

The example configuration below shows a typical configuration where an external analog motor amplifier is to be used with differential encoder feedback and optically isolated limit switches.

Note the areas on the screen circled in red.

The Axis input type has been selected as "Encoder" with the first Input channel set to 0 (Encoders only use one input channel). A differential encoder should then be connected to Kanalog JP3 A0+ A0- B0+ B0-.

The Axis Output type has been selected as "DAC Servo" with the first Output channel set to 0 (DAC Servos only use one output channel). The Motor's Amplifier should then be connected to Kanalog DAC0 JP11 pin 1 (and ground).

Limit Switch Options have selected I/O bits 136 and 137 which are Kanalog Opto Inputs 0 and 1 on JP15 across pins 1&2 and 3&4.

## KONNECT - Connector Pinouts

J1 Input Commons

## Konnect JP8 Aux Bus Connection to KFLOP JP6

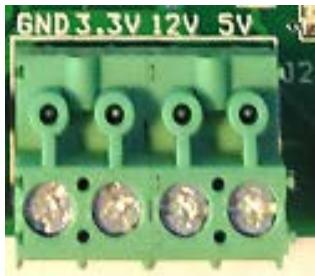

JP8 provides all internal signal and power connections to KFLOP. This 16 pin ribbon connection should be as short as possible to avoid noise and crosstalk as the cable forms a high speed communication link. The Aux Bus supports multiple boards connected to the same cable. In most case the specifics of the Aux Bus will be handled internally by KFLOP and no knowledge of the signals will be required for use.

The 8 data bits (DB0-DB7) are bi-directional. CLKIN and STARTIN allow a board to be selected by the address placed on the bus, and then a fixed sequence of 8-bit writes (2) and reads (5) can be performed using the CLKIN signal.

Pin	KFLOP Name	Konnect Name
1	VDD5	VDD5
2	VDD12	VDD12
3	VDD33	VDD33
4	RESET#	RESET#
5	IO26	DB0
6	IO27	DB1
7	IO28	DB2
8	GND	GND
9	GND	GND

13	IO32	DB6
14	IO33	DB7
15	IO34	CLKIN
16	IO35	STARTIN

## J2 Konnect Power

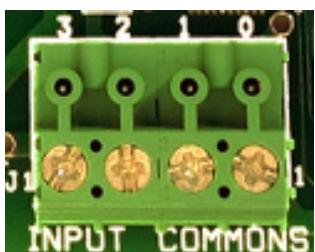

The power signals from KFLOP's Aux Bus are available on the J2 terminals. It is not normally necessary to apply power to these terminals as power is supplied from KFLOP through the JP8 connector. For multiple boards it may be desirable to apply additional higher gauge power and GND connections between boards. Note the Signal labeled 12V is connected to the KFLOP 12V signal but may not be necessarily 12V. KFLOP and Konnect do not require or use the 12V signal but only pass the signal through the various connectors. Disk Drive Power Supplies usually supply +12V into KFLOP JR1 Pin 1. Also note that if any of these supply voltages are used for the Inputs or outputs then the Input wiring will not be isolated from KFLOP.

It is possible to supply +5V power to KFLOP through these terminals if the power consumption on KFLOP is less than 1 Amp and the ribbon cable connection is short (several inches or less).

## Optically isolated Inputs

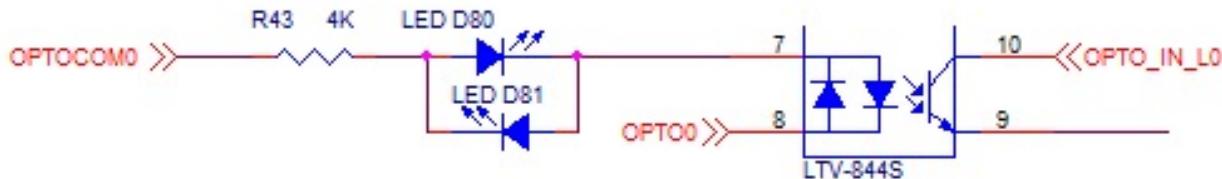

Individual Inputs (one of 4)

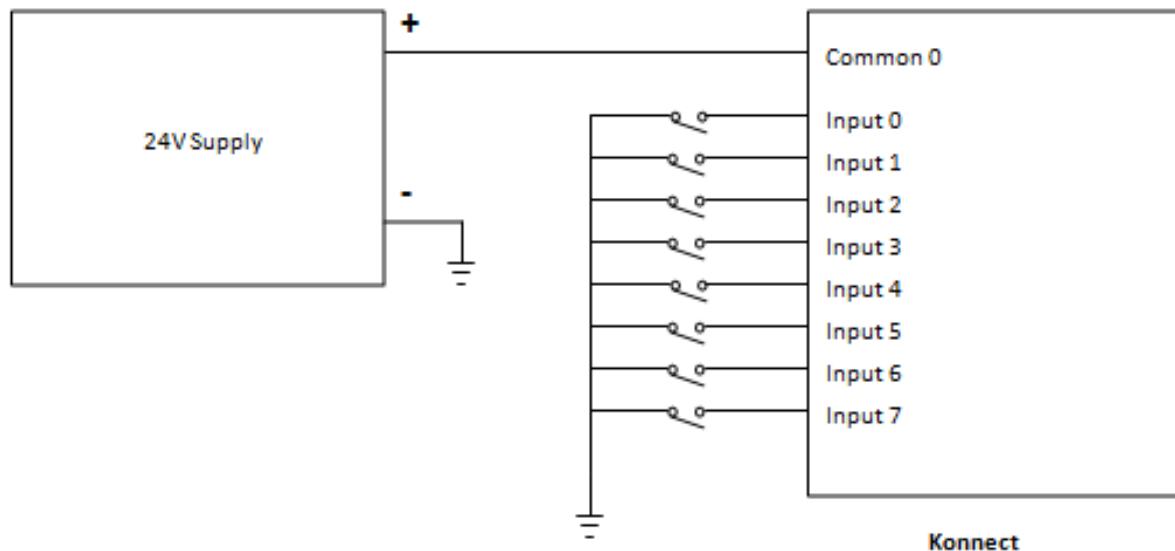

Input Bank Commons

Konnect's 32 optically isolated inputs are grouped into 4 independent Banks of 8 inputs. This allows any Bank to be used with either sourcing or sinking signals. However all inputs in the same bank share the same common and must operate in the same mode. The 4 independent Banks also allow different supply voltages and supply isolation to be used for each Bank. 24V is the preferred input voltage and will draw  $(24V - 1.4 - 1.4)/4K \sim 5\text{ma}$  of current.

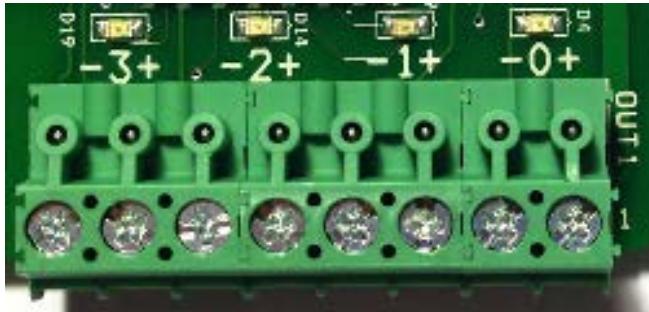

Konnect's 32 optically isolated inputs can be driven from a +/- 4.75V to a +/-25V signal. Less than 2V should be applied to ensure the input is off. One of the 32 input circuits is shown below. The input consists of a AC type of Optocoupler in series with an LED indicator in series with a 4Kohm resistor. The AC type of input allows the common to be connected to either the Positive or Negative Supply voltage so that either sinking or sourcing outputs can be used (current can flow either direction to activate the input).

External Wiring would typically be arranged such as:

## ***Opto Isolated Outputs***

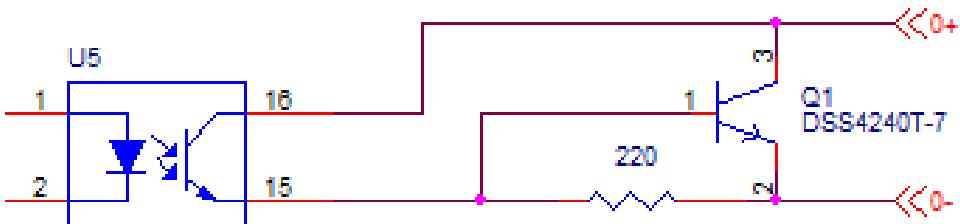

### **Input Bank Commons**

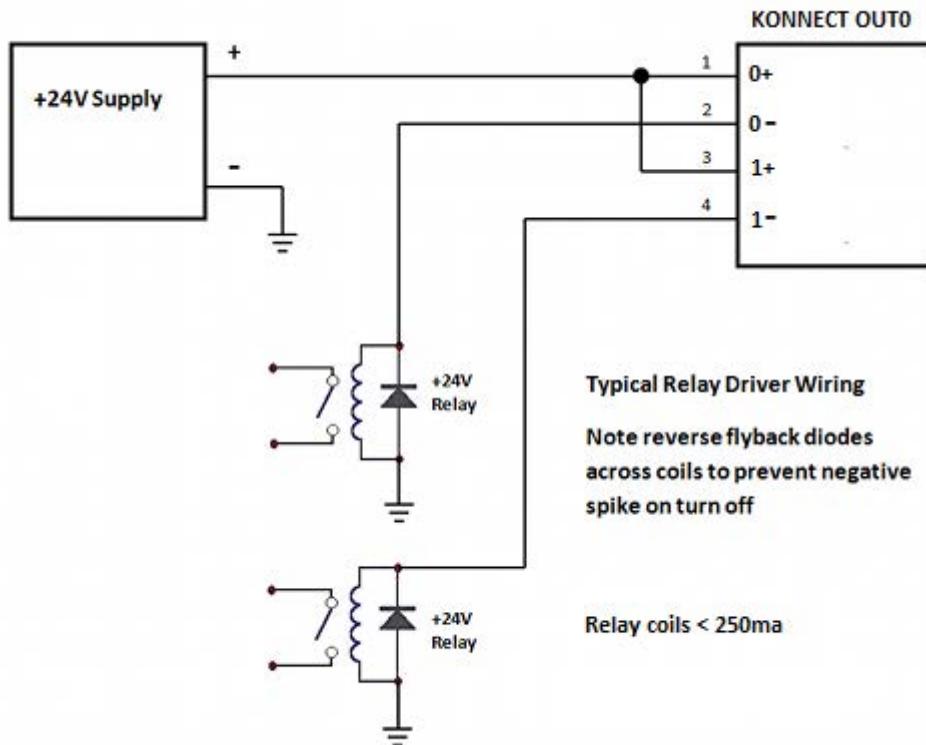

Each of the 16 Optically Isolated Outputs is completely isolated with a + and - terminal. When active the output passes current from the + to - terminals much like a relay contact would.

The Outputs are capable of driving medium power devices such as relay coils. Loads up to 30V @ 250mA may be driven.

The internal Konnect Output Circuitry is shown below which converts a photo transistor output to darlington transistor output. The 220Ohm resistor allows the output to have a low on voltage for low currents before the transistor turns on. This allows the output to drive low current circuits with a smaller on voltage(2ma @ < 0.6V). For example LVTTL/TTL inputs require less than 0.8V to guarantee a low input. At higher currents Q1 becomes active and keeps the on voltage drop below 0.9V at 0.25A. Switching 0.25A at 24V allows loads up to 6W to be driven.

A typical wiring diagram driving 24V relays. Because of the less than 0.9V drop on the Konnect outputs the load will be driven with more than 23.1V.

### Board Address Selection Jumpers

The KFLOP's Auxiliary Port works as a Bus where multiple boards can be connected to the same Port. Each board has an address so it can be selected as active. For a single Konnect board in the system removing all Jumpers will configure the Konnect Board Address as zero. If multiple boards are to be used set each board to a unique address.

A0	A1	A2	Address
Removed	Removed	Removed	0
Installed	Removed	Removed	1
Removed	Installed	Removed	2
Installed	Installed	Removed	3
Removed	Removed	Installed	4
Installed	Removed	Installed	5
Removed	Installed	Installed	6
Installed	Installed	Installed	7

KFLOP can be configured to service each Konnect Board using the AddKonnect function. The first parameter is the board address. The second parameter is the address of where KFLOP should obtain data to send to Konnect's 16 Outputs. The 3rd Parameter the address of where KFLOP should place the data received from Konnect's 32 Inputs.

In most cases the addresses will be KFLOP Virtual I/O bit locations. KFLOP has two sets of Virtual I/O Bits, standard and extended. The standard consists of 16 Bits in VirtualBits, and the Extended consist of 1024 Bits in VirtualBitsEx[32].

The code below configures KFLOP to service 4 Konnect Boards (192 IO bits):

```
InitAux();
AddKonnect(0,&VirtualBits,VirtualBitsEx);
    AddKonnect(1,VirtualBitsEx+1,VirtualBitsEx+2);
    AddKonnect(2,VirtualBitsEx+3,VirtualBitsEx+4);
    AddKonnect(3,VirtualBitsEx+5,VirtualBitsEx+6);
```

Board 0 has Output Bits mapped to 48 - 63 and Input Bits Mapped to 1024-1055  
 Board 1 has Output Bits mapped to 1056-1071 and Input Bits Mapped to 1088-1119  
 Board 2 has Output Bits mapped to 1120-1135 and Input Bits Mapped to 1152-1183  
 Board 2 has Output Bits mapped to 1184-1199 and Input Bits Mapped to 1216-1247

### ***Typical IO Mapping for Standard Single Konnect***

## KONNECT Block Diagram

## KONNECT Board Layout

## KONNECT - PWM to Analog Example

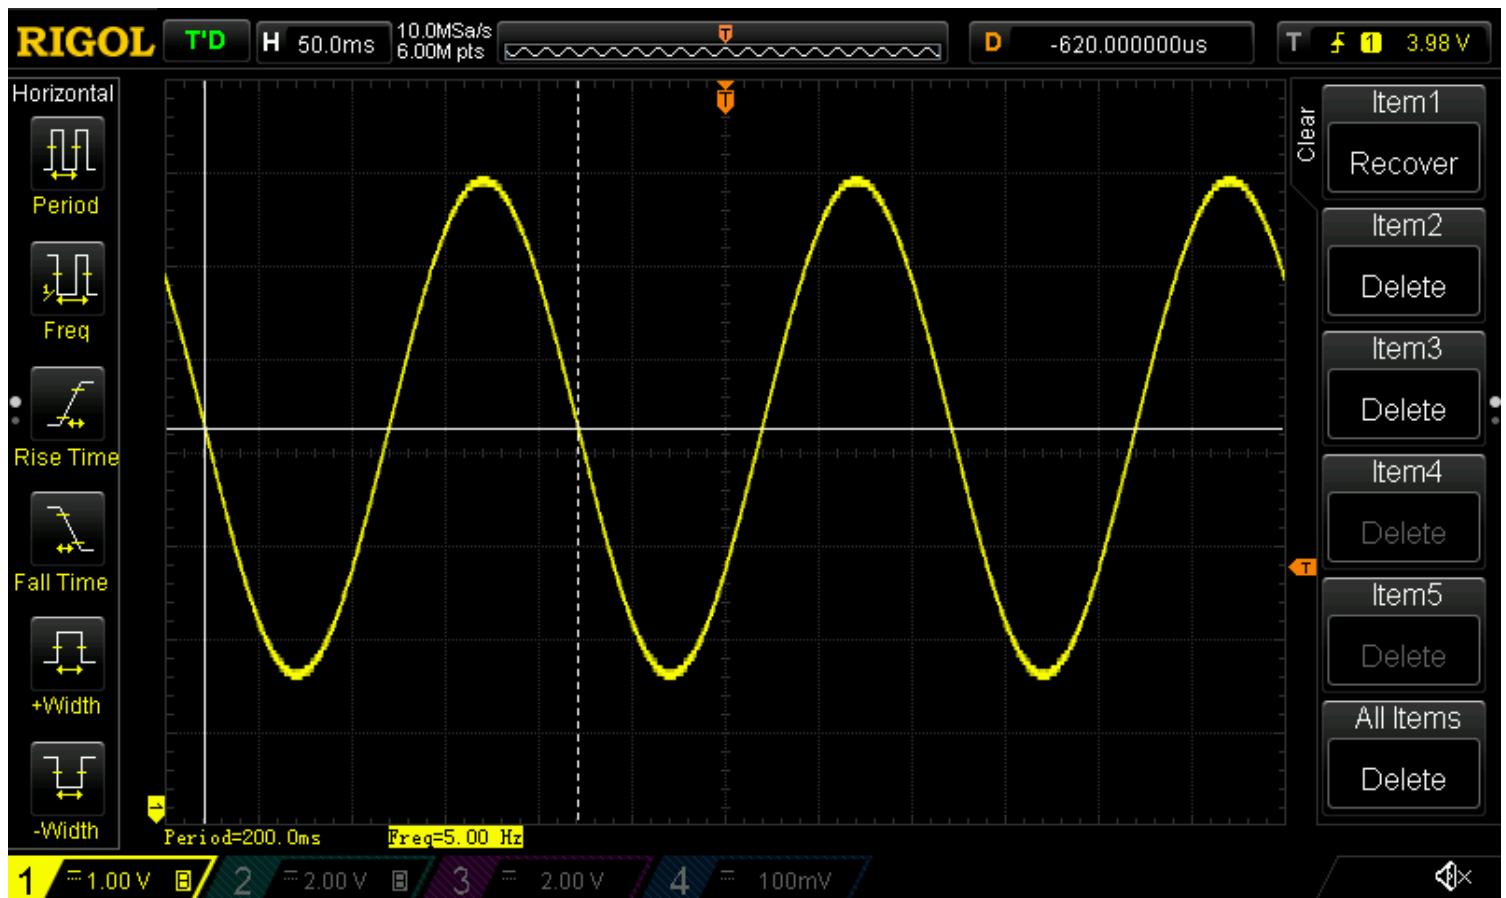

KFLOP+Konnect+Simple Filter Circuit can be used to produce a programmable analog signal. This might be used as a basic Spindle Speed Control Signal if no others are available.

This demonstrates the flexibility of the Konnect Outputs which are Isolated, can sink or source current, fast, medium power, and low impedance

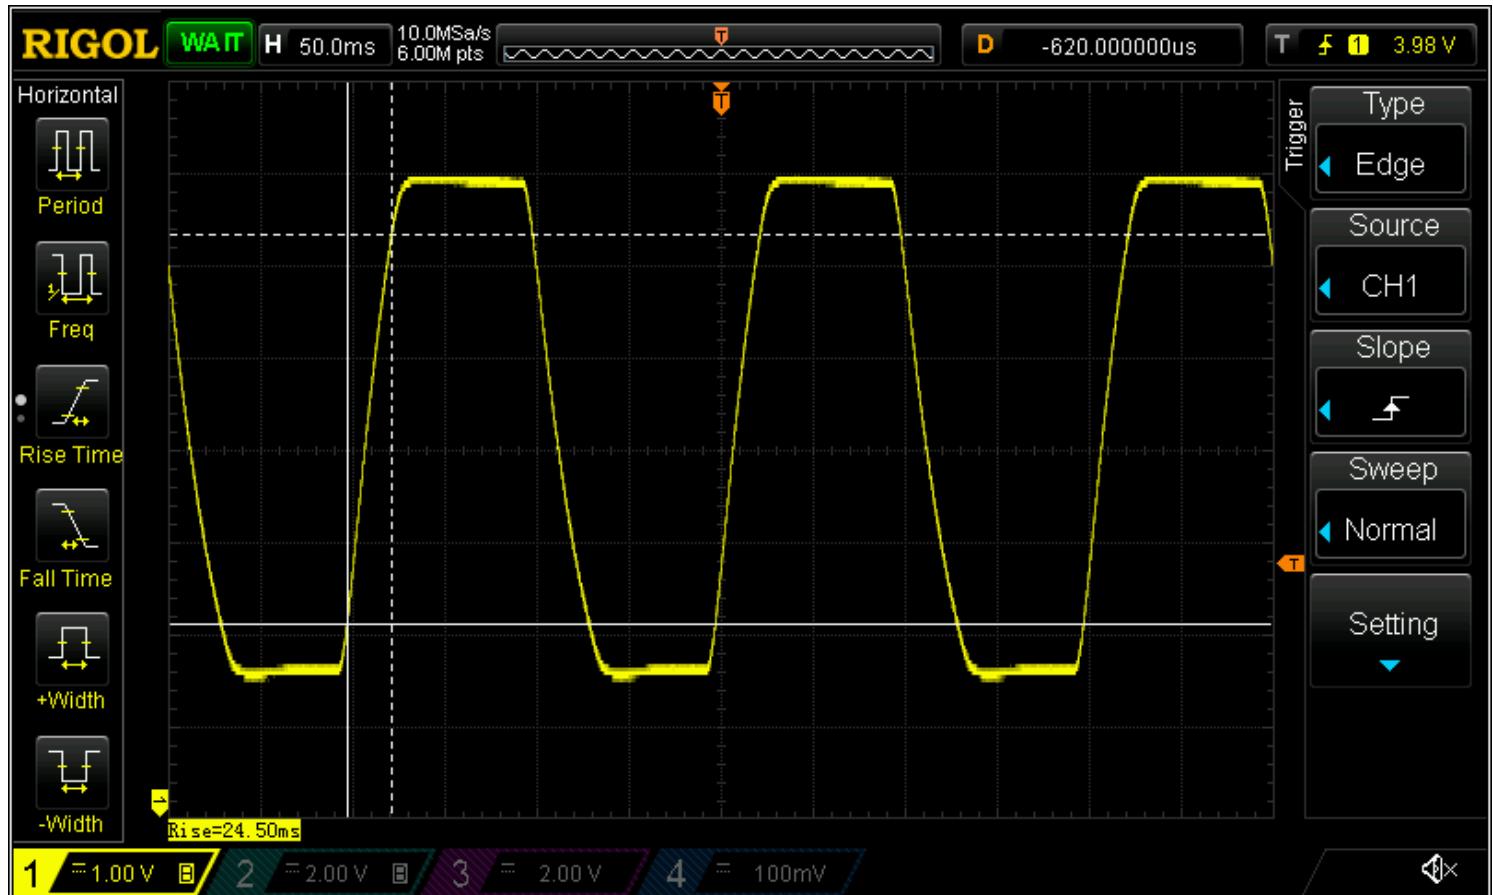

### Results

Analog Oscilloscope traces of Analog signals generated by a KFLOP Software generated PWM Signal controlling two optically isolated Konnect Outputs that are then passed through a simple low pass filter.

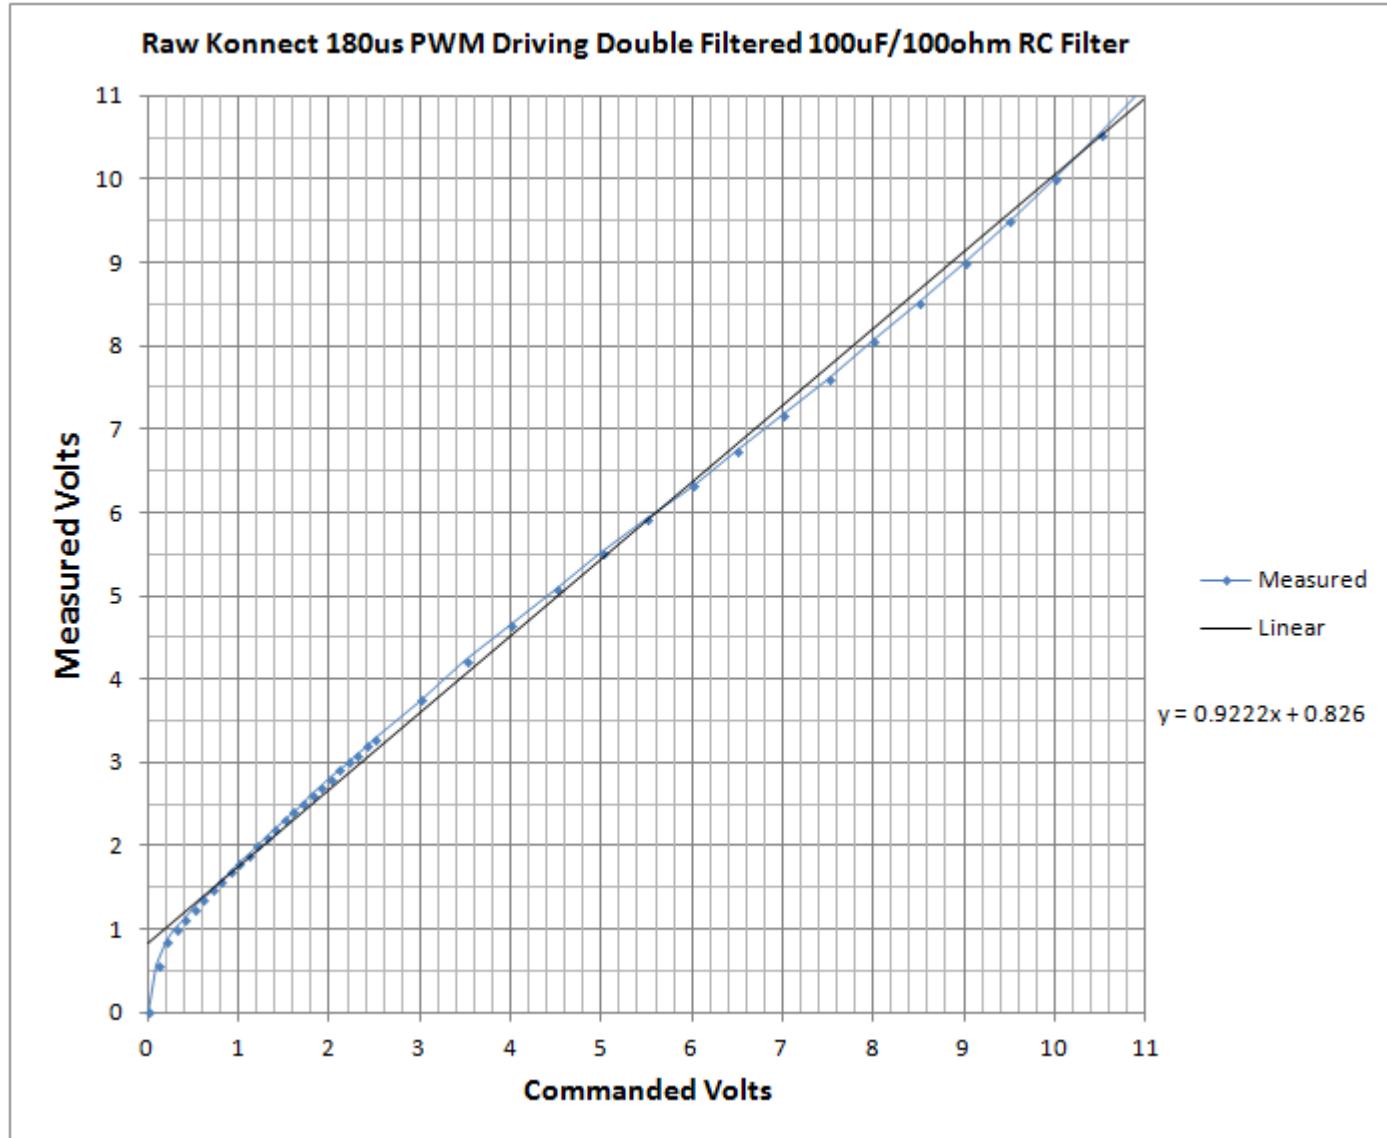

High resolution and response rates easily usable for speed control applications

Square wave to test large signal changes. Significant change in < 25ms

Reasonable linearity. This would require calibration if higher accuracy is needed.

## Circuit

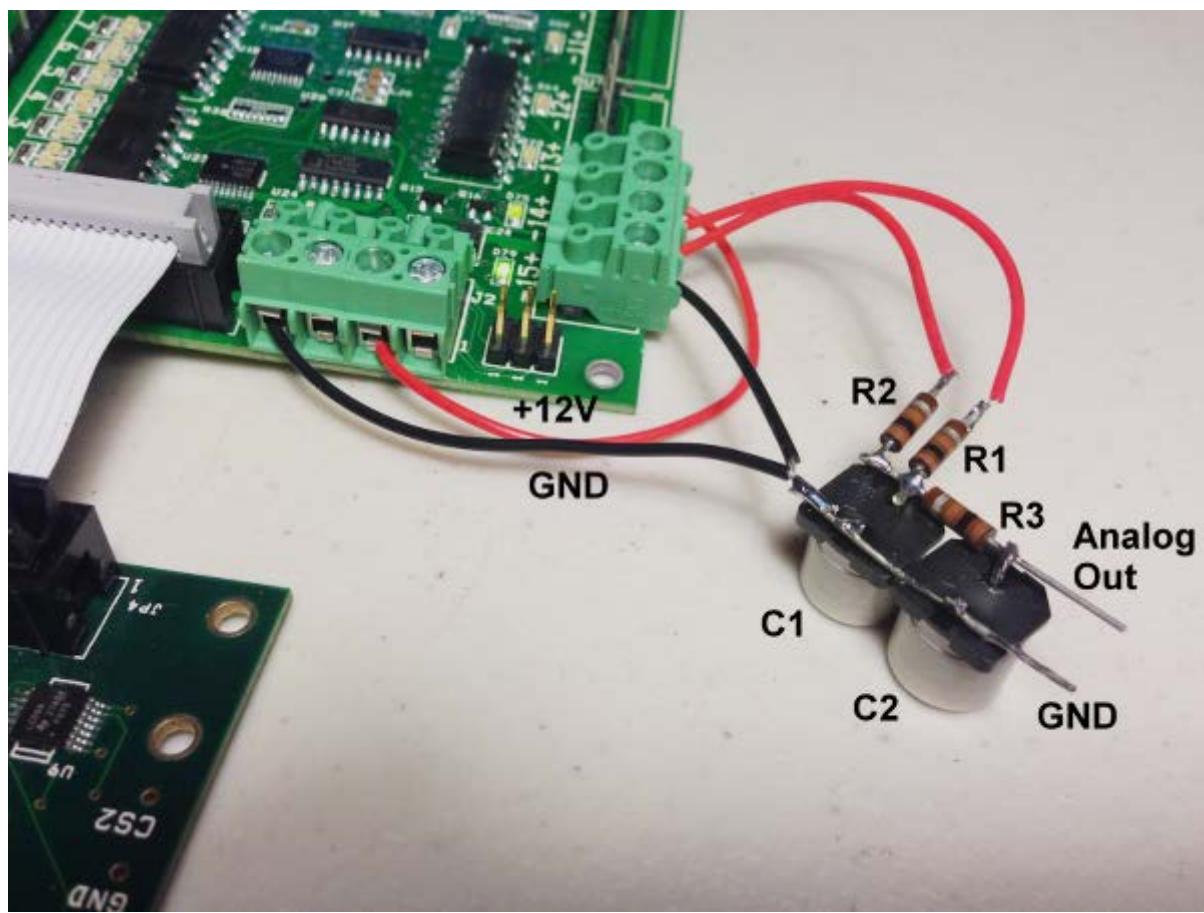

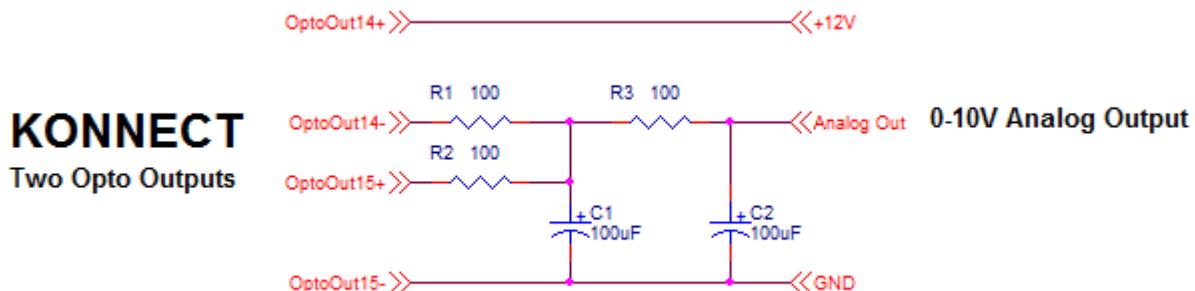

Simple cascaded dual low pass filters. Only 5 components. One resistor type and one capacitor type. Component values are not critical (R1 and R2 should be matched).

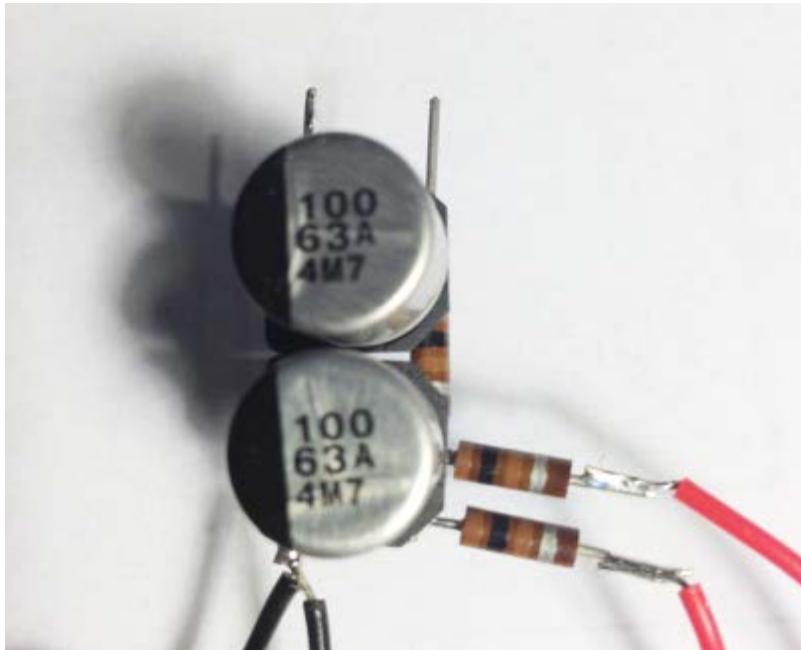

One Konnect Output charges the capacitors and one output discharges them. Both should not be turned on simultaneously (but no damage will occur if they are as R1+R2 will limit the current).

The relatively low resistance values (100 Ohms) provides low output impedance so that any connected load should have a minimal effect. A load of 10Kohms or higher should work well.

Double filtering provides low output ripple, while still having relatively quick response to changes, uses reasonably small capacitors, even with relatively low PWM rates.

Konnect Outputs can be updated every 180us. So 180us is the basic PWM quantum. This results in ~ 10mV p-p ripple..

## Software

This software example simulates how an RC circuit would respond to an applied, switched, high/low voltage.

If the simulated voltage is below the desired output voltage then the output is switched high to charge up the capacitor, otherwise it is switched low to discharge the capacitor.

The same state that is simulated is also sent to the Konnect Outputs to drive the real circuit. The real circuit is a bit more complex but the simple model works reasonably well. The two RC circuits will eventually evolve to the same voltage as the average PWM Voltage in the steady state. Only the transient response will be slightly different. Similarly, somewhat incorrect component values will only affect the transient response. The program values were adjusted to get the best response.

The #define statements may require changes for your specific circuit and I/O Bit used.

The Vout value is coded to create a sine wave, but more typically the value would be passed in through a global persist variable as a Spindle Speed Setting.

```
#include "KMotionDef.h"

// Enables a Konnect on KFLOP JP4 Aux Port then
// PWM's two outputs as push-pull drivers such that
// when low passed filtered with an RC circuit becomes
// a variable analog source.
//
```

```

// Configure KFLOP to service Konnect 32 Input 16 output IO board
// Board address is 0,
// 16 Outputs are mapped to Virtual IO 48-63 (VirtualBits)
// 32 Inputs are mapped to Virtual IO 1024-1055 (VirtualBits[0])
//
// Attach Service to Aux0 Port (KFLOP JP4) instead of standard Aux1 Port
(KFLOP JP6)

## Using SnapAmp 1000

*SnapAmp is a very high performance, feature rich, efficient amplifier that expands the capability of the KMotion Motion Control System.*

A SnapAmp adds:

- PWM Amplifier channels
- Opto isolated Inputs
- Differential Encoder inputs
- General Purpose digital IO
- Real-time current measurement for each motor coil
- Real-time power supply voltage measurement
- Programmable peak Supply Current limits
- Programmable power supply voltage clamping
- Digital temperature monitoring

Up to two SnapAmps may be added to a Single KMotion Controller.

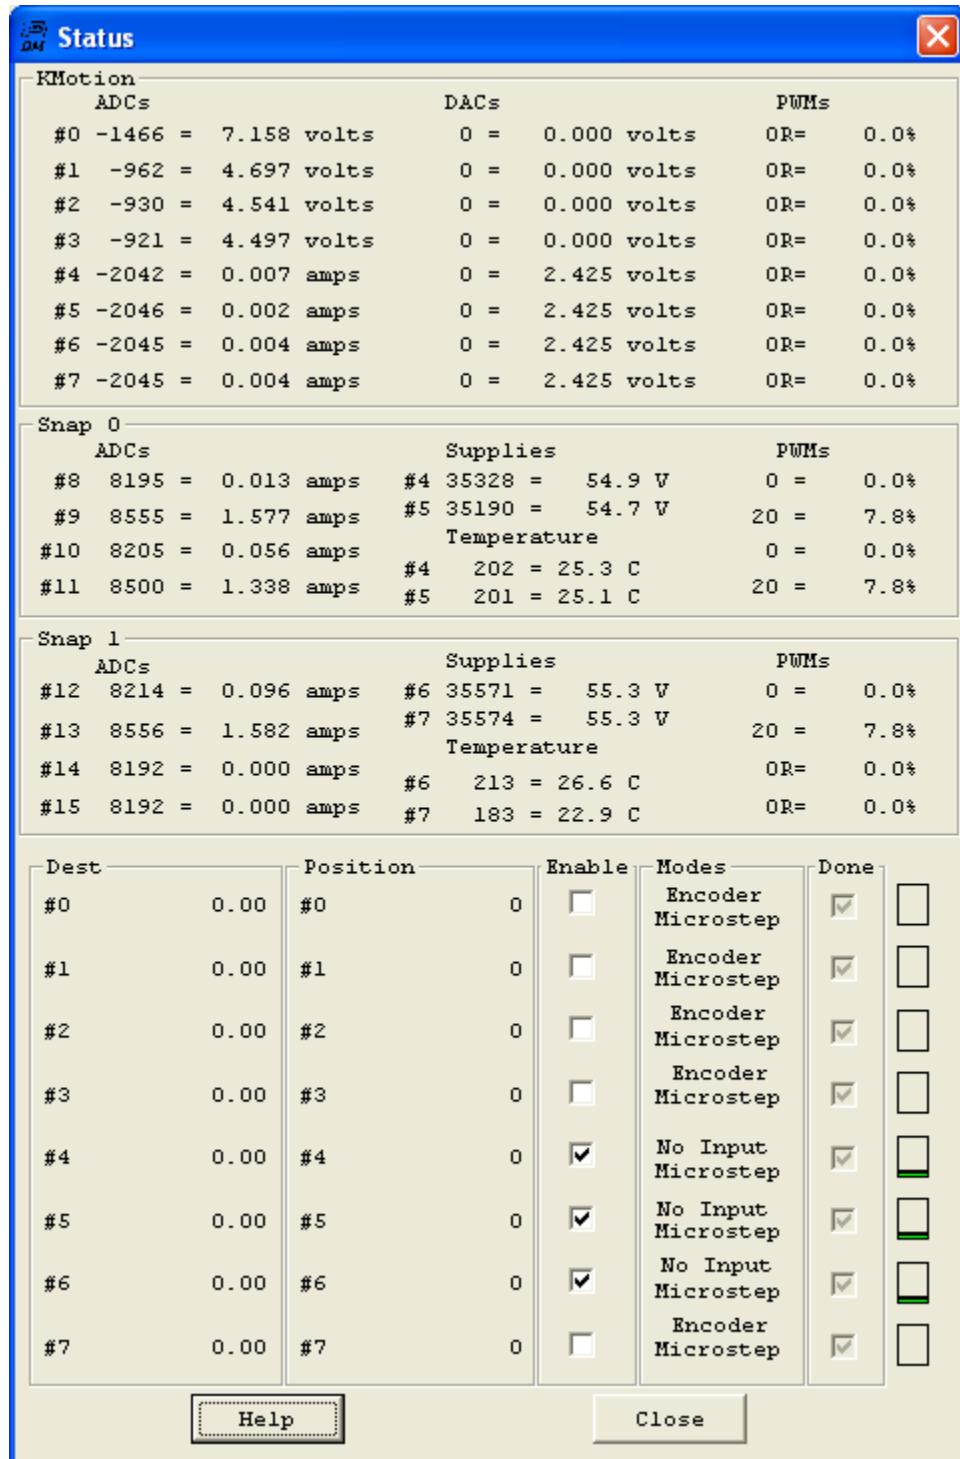

A single SnapAmp adds four PWM full bridge amplifiers. The four PWM's are identified as 8,9,10,11 for the first SnapAmp in a system and 12,13,14,15 for a second SnapAmp in a system. A single PWM/Full bridge is required for a brush motor, and a consecutive pair of PWM/Full Bridges are required for a Stepper Motor or Brushless Motor.

A single SnapAmp adds four Quadrature Encoder inputs. The four Quadrature Encoder inputs are identified as 8,9,10,11 for the first SnapAmp in a system and 12,13,14,15 for a second SnapAmp in a system.

Within the KMotion executive program under the option menu set whether there are one or two SnapAmps connected to KMotion. This enables expanded Analog and Digital Screens that will then display the additional I/O available on the SnapAmp(s).

The middle portion of the Analog Status Screen displays the measured currents, supply voltages, temperatures, and current PWM settings.

The Digital I/O screen displays the IO bits (numbers 64 - 93) for SnapAmp 0 in the middle portion of the screen, and IO bits numbered (96 - 125) for Snap Amp 1 on the right portion of the screen. The original KMotion I/O bits remain on the left portion of the screen. Note that KMotion I/O Bits 20-28 are used for the high speed communication to the SnapAmps and may not be used as user IO.

Digital I/O

SnapAmp has programmable peak current limiting and also programmable peak supply voltage clamping. The clamping is required for large machines because when a massive machine stops quickly, the mechanical energy ends up getting injected back into the power supply. Some power supplies don't like this and allow their voltage to rise up possibly causing damage to the supply or the SnapAmp. The clamping feature protects against this. Currently there isn't a way to configure the current limits and voltage clamp from the KMotion Screens. Listed below is a small C program that may be used to set them appropriately for most systems. Snap Amp has 2 green LEDs. One just blinks to say it is alive and running. The other turns on for a fault condition. A fault can be an over current or over temp. When a fault condition is present, all amps are disabled. When you power up KMotion the fault LED should be on until you run the program and the current limit is set.

SnapAmp peak current limiting is measured from the Motor Supply high side terminal. High side supply measurement is preferred for short protection because most wiring shorts to ground are detected and properly trigger a fault. SnapAmp measures both High side and Low side currents. The Low Side current measurement is made specific to each motor lead, digitized with a precision 10-bit ADC and available for plotting. High Side current measurement is fairly crude with a few programmable thresholds for detecting catastrophic events such as shorts and stalls. Threshold levels 9 through 15 set the approximate fault threshold. The lowest value that allows proper operation of your system without faults should be used. The Table below lists the approximate fault current thresholds for levels 9 through 15. The default power up value of 0 will generate a continuous fault until set to the appropriate value. Note that if either of the two power supply peak current detectors are over threshold the entire SnapAmp board (all 4 full bridges) will be disabled. When a fault occurs all full bridges will be disabled for approximately 1/4 second, after which the board will be automatically re-enabled until another fault is detected. Note: Since any over current fault disables the amplifier for 1/4 second, whenever a fault is cleared, including when the level is initially changed from zero, a delay of 1/2 second should be made before attempting any motion.

Approximate Peak Current Thresholds:

Level	Amps
-------	------

9	2
10	6
11	10
12	14
13	18
14	22
15	26

Below is an example C program that must be loaded and executed in the KMotion Board to set the Peak Current limits for each motor supply (to threshold level 9 in this example) and to set the Supply voltage clamp level (to 90V in this example). The Supply Voltage clamping level should be set several volts higher than the actual supply voltage. The example shows setting the values on the first SnapAmp. To set values on the second snap amp replace the symbol SNAP0 with SNAP1.

```
#include "KMotionDef.h"
main()
{
    // peak current limits
    WriteSnapAmp( SNAP0+SNAP_PEAK_CUR_LIMIT0 , 9 );
    WriteSnapAmp( SNAP0+SNAP_PEAK_CUR_LIMIT1 , 9 );
    // clamp supply to 90V
    WriteSnapAmp( SNAP0+SNAP_SUPPLY_CLAMP0
        ,SNAP_CONVERT_VOLTS_TO_ADC( 90.0 ) );
    WriteSnapAmp( SNAP0+SNAP_SUPPLY_CLAMP1
        ,SNAP_CONVERT_VOLTS_TO_ADC( 90.0 ) );
    // enable supply clamping
    WriteSnapAmp( SNAP0+SNAP_SUPPLY_CLAMP_ENA0 , 1 );
    WriteSnapAmp( SNAP0+SNAP_SUPPLY_CLAMP_ENA1 , 1 );
}
```

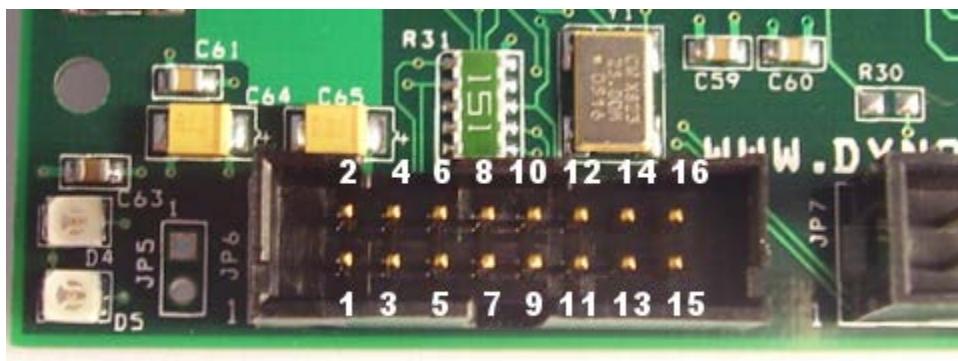

## SnapAmp - Connector Pinouts

SnapAmp contains three connectors labeled JP1, JP6, and JP7.

### **JP6 - KMotion Communication & Logic Power**

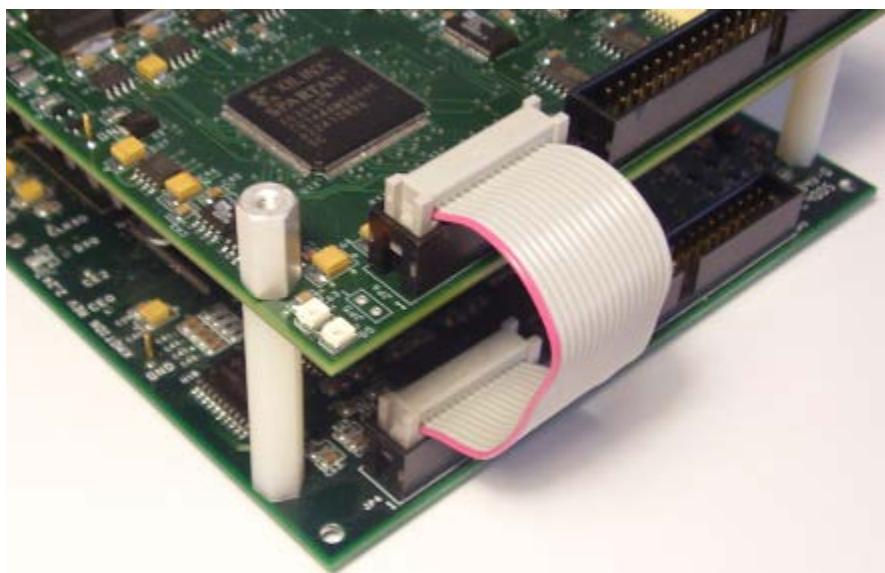

JP6 is a proprietary high-speed communication bus where command and status communication between the KMotion board and the SnapAmp Amplifier. Up to two SnapAmps may be attached to a single KMotion Board. The second of the two SnapAmps must have a configuration jumper installed into JP5.

This connection is required for proper operation of the SnapAmp and should be as short as possible.

16 pin ribbon cable connection between SnapAmp and KMotion.

Note: 4 - 40 x 1 3/8 inch standoffs are used between SnapAmp (top) and KMotion (bottom).

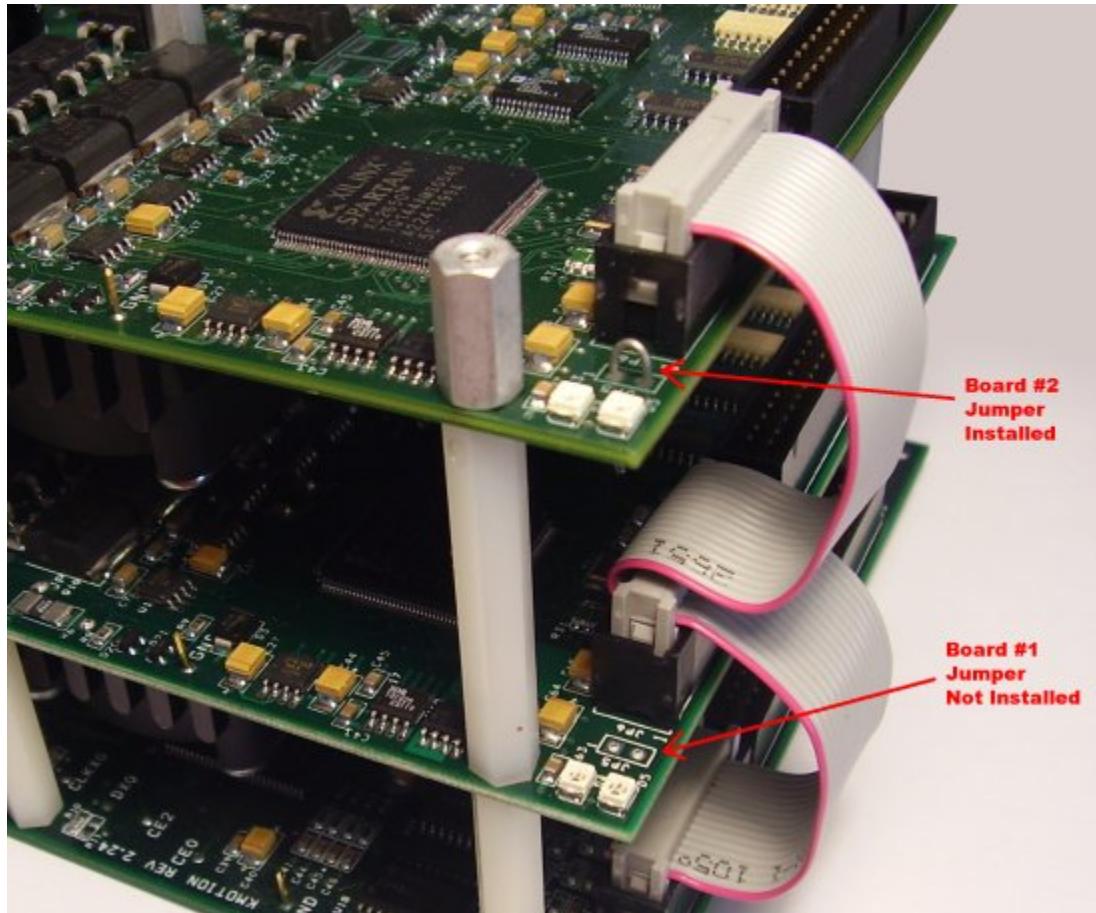

16 pin ribbon cable connection between Dual SnapAmps and KMotion

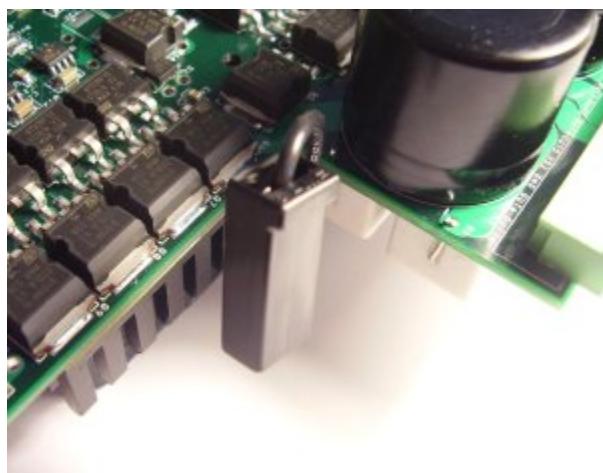

**Notes:**

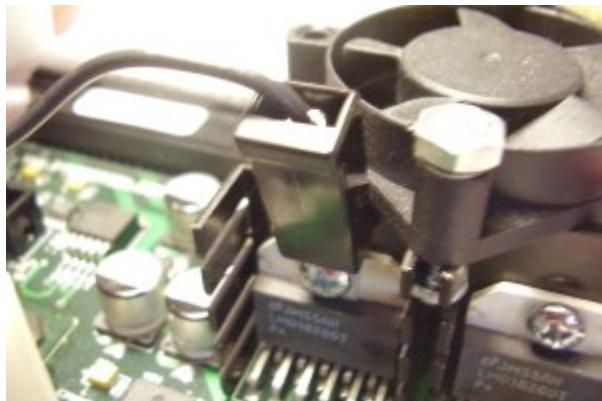

- 4 - 40 x 1 3/8 inch standoffs are used between SnapAmp and KMotion
- 4 - 40 x 1 5/8 inch standoffs are used between SnapAmps

JP5 Jumper installed configures a SnapAmp as the 2nd SnapAmp.

When attaching SnapAmp to the KMotion first attach main ground plug as shown.

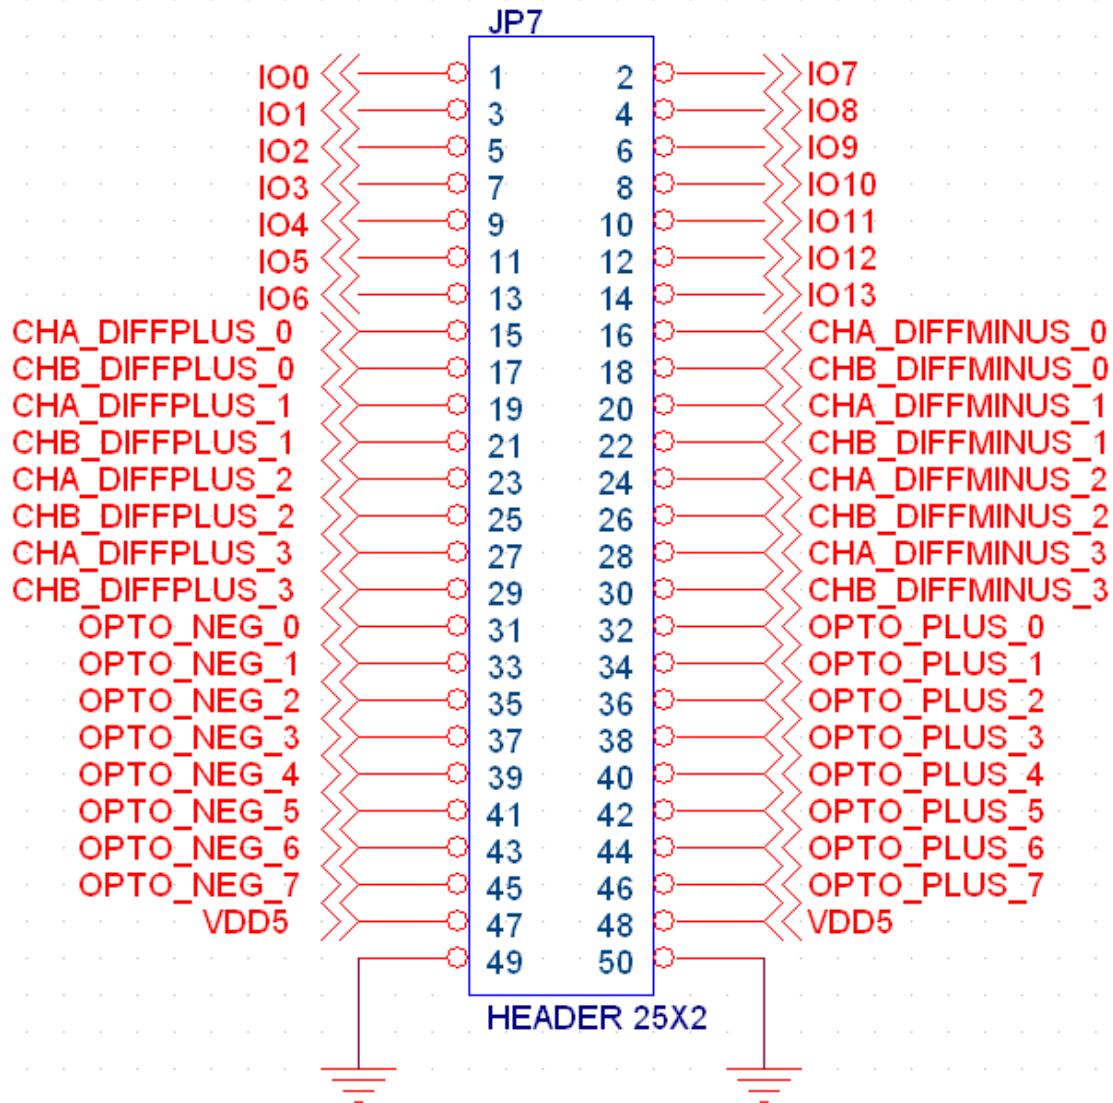

For Dual Snap Amp systems attach the 1:2 spade Y adapter before connecting the first SnapAmp

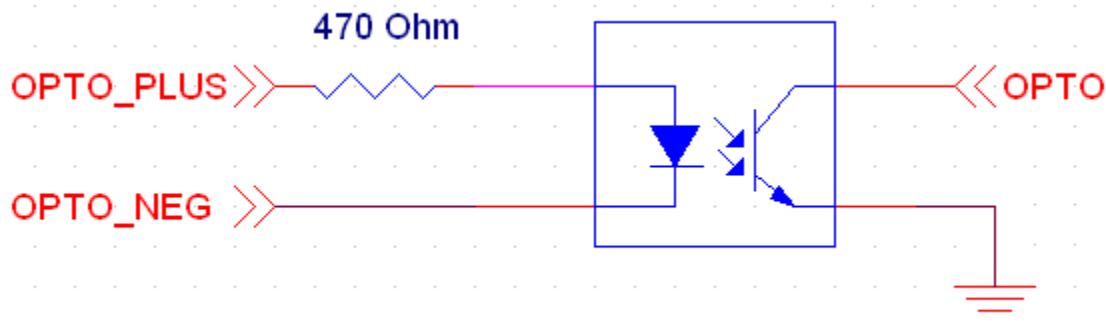

#### ***JP7 - I/O - General Purpose LVTTI - OPTO Isolated - Differential - Encoder Inputs***

JP7 Is used for all Digital I/O. Fourteen General Purpose LVTTI I/O, Eight Differential Encoder Inputs, and Eight Optically Isolated Inputs.

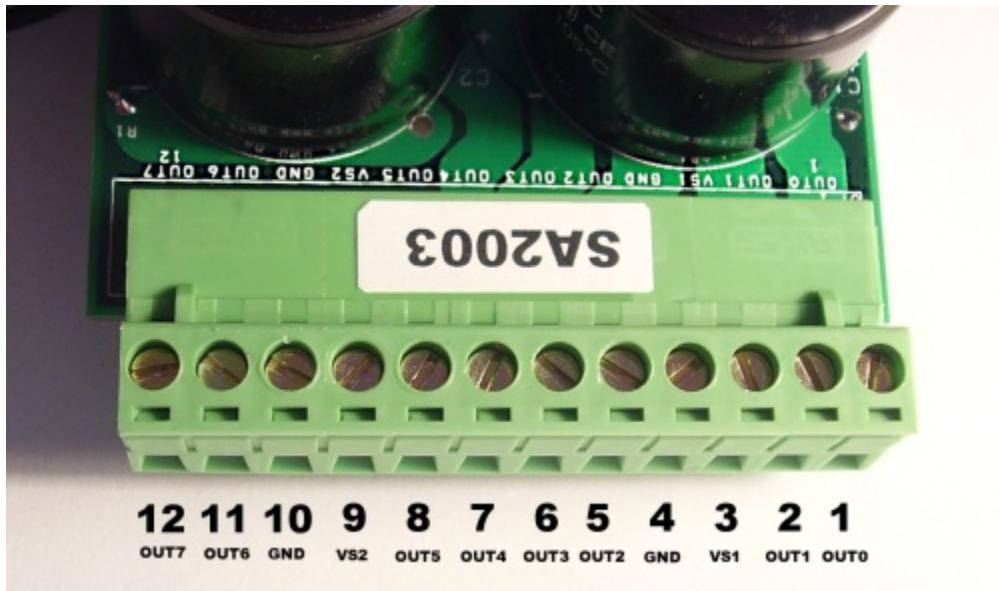

Optically isolated input circuit. 5-12V may be applied. Current requirements at 5V is approximately 6ma and at 12V is approximately 20ma. SnapAmp Opto inputs have negative true polarity (energizing the Opto is read as a Logic 0 in KFLOP).

## SnapAmp Stepper Motor Diagnostic Tutorial

Shown below is a plotted motion of 400 cycles (1600 full steps) with quite gradual acceleration up to a velocity of 255 cycles/sec (1000 sps)

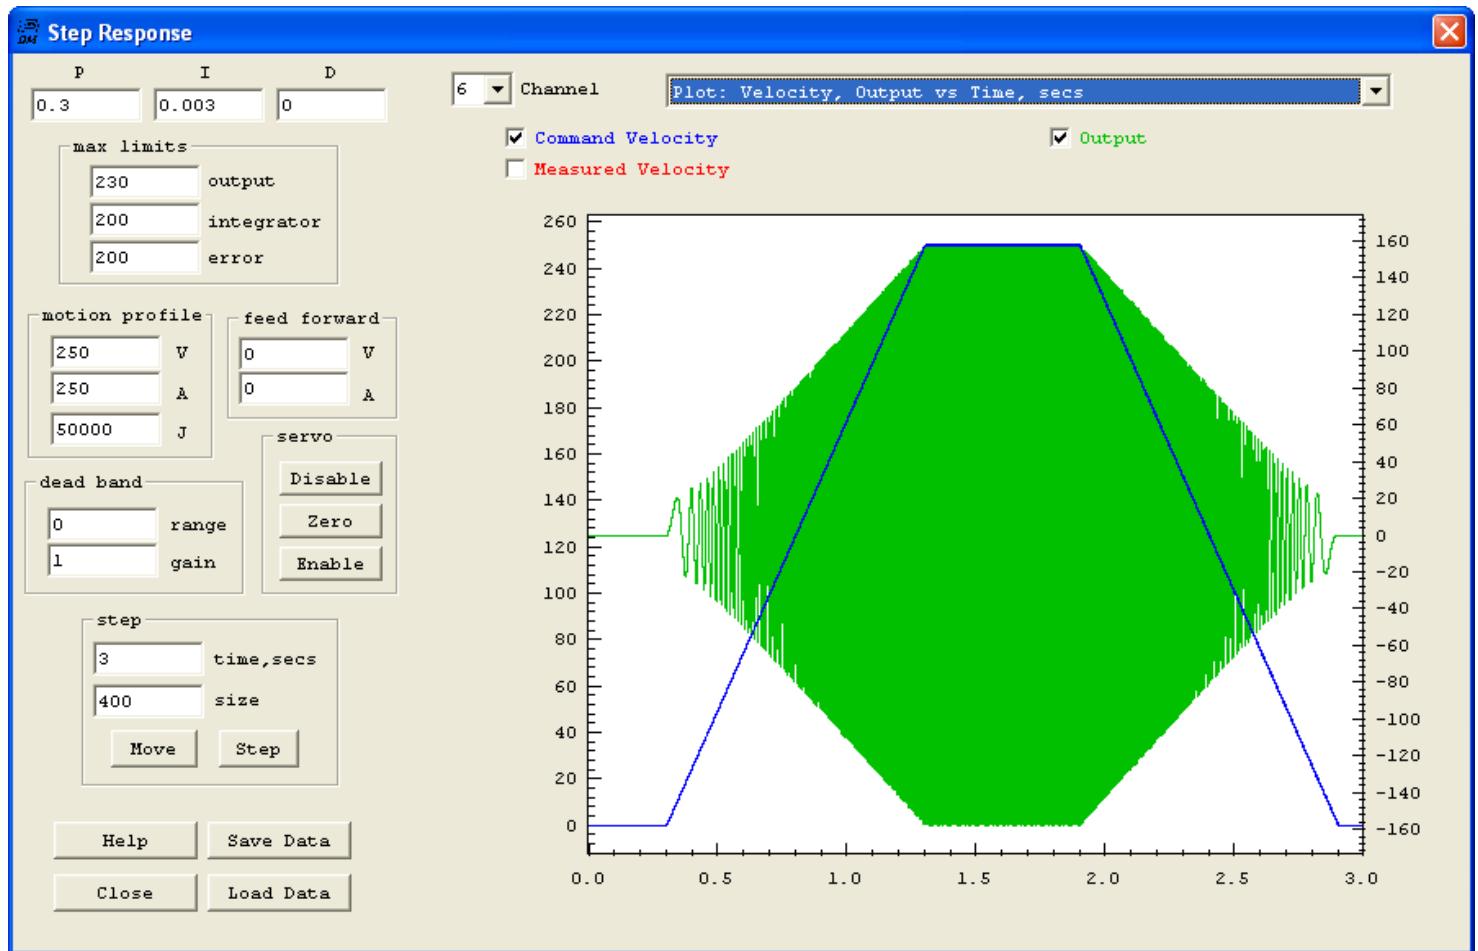

A noise from the motor is heard during about the middle half of the motion. Here the motor position and current in both stepper coils is plotted.

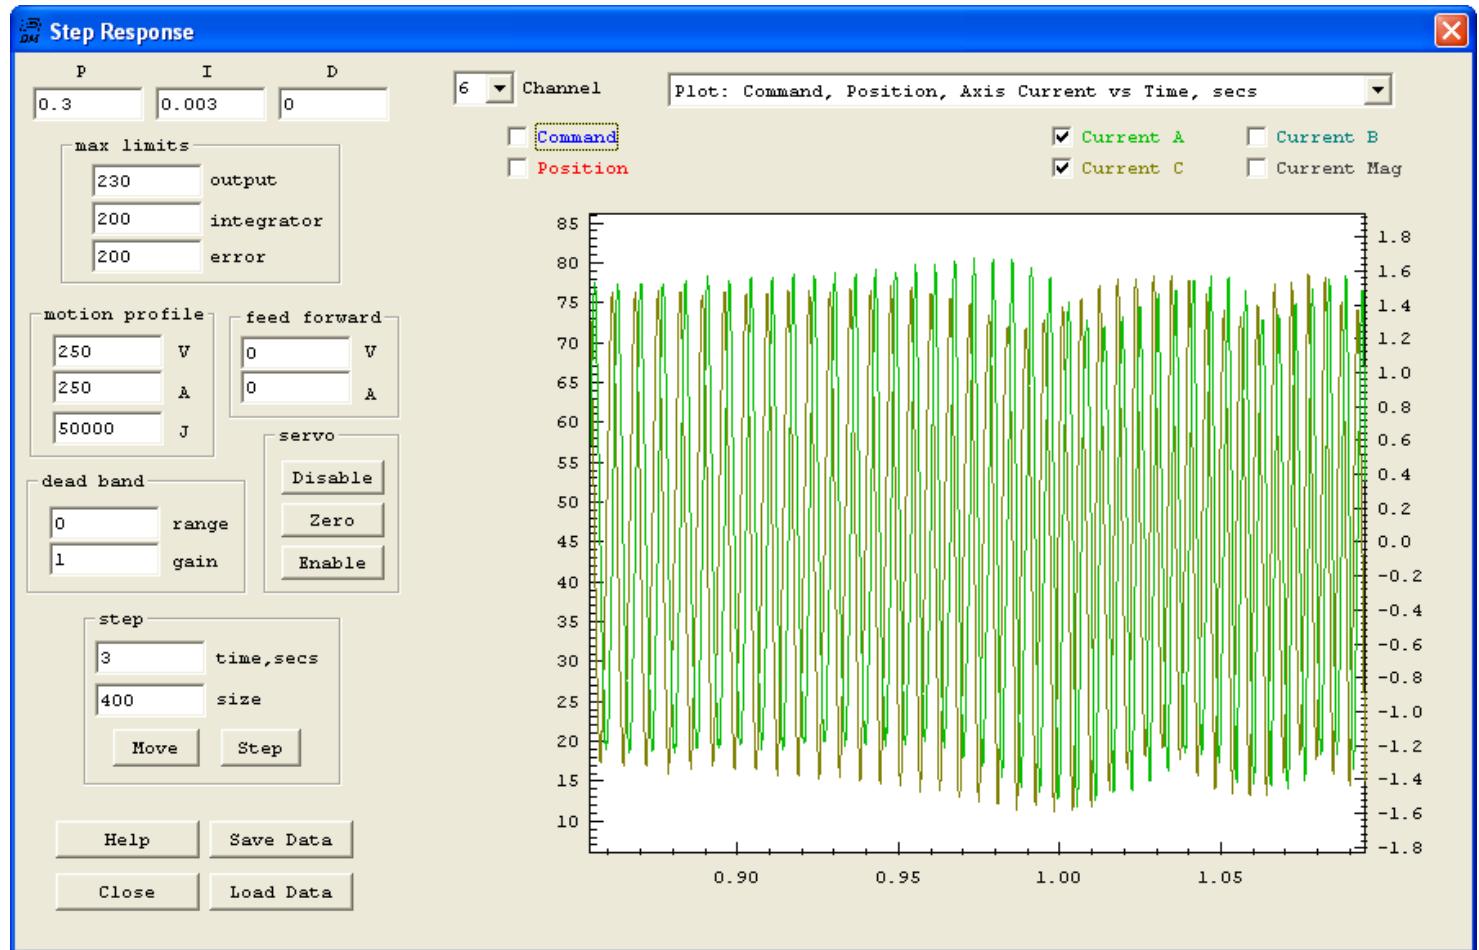

Zooming in on the beginning of the motion shows nice current waveforms 90 degrees out of phase.

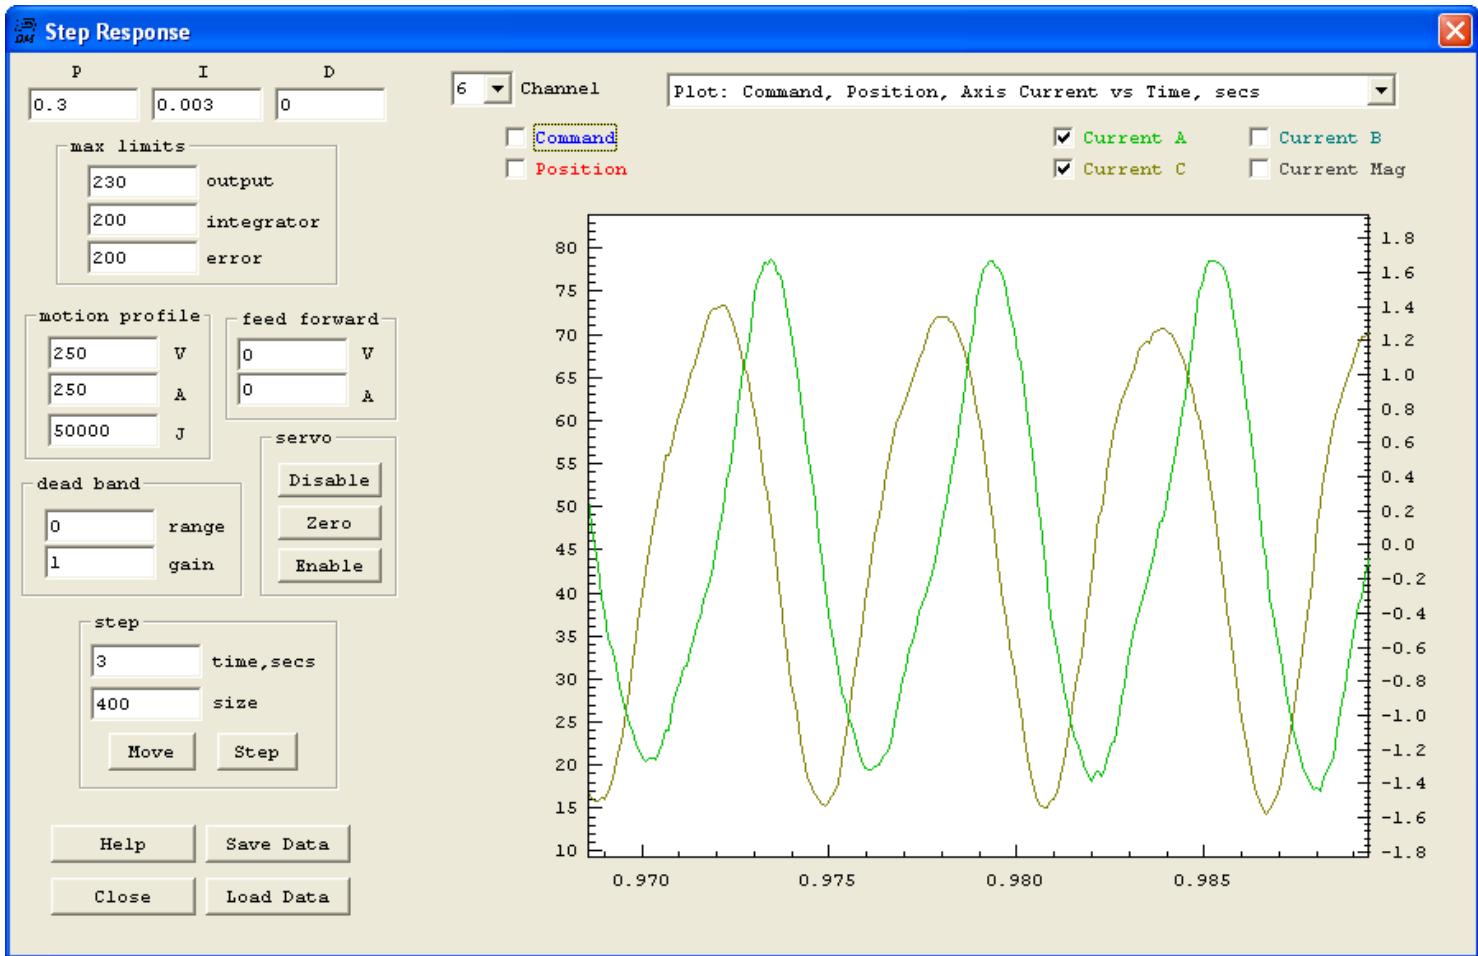

Here is a plot of the Velocity and the commanded output Voltage of one of the coils. Note how as the Velocity increases the lead compensation (set at 55) increases the amplitude. Referring back to the first current plot above we can see that the current amplitude is maintained at about 1.4 amps throughout the motion. Showing the lead compensation is set properly.

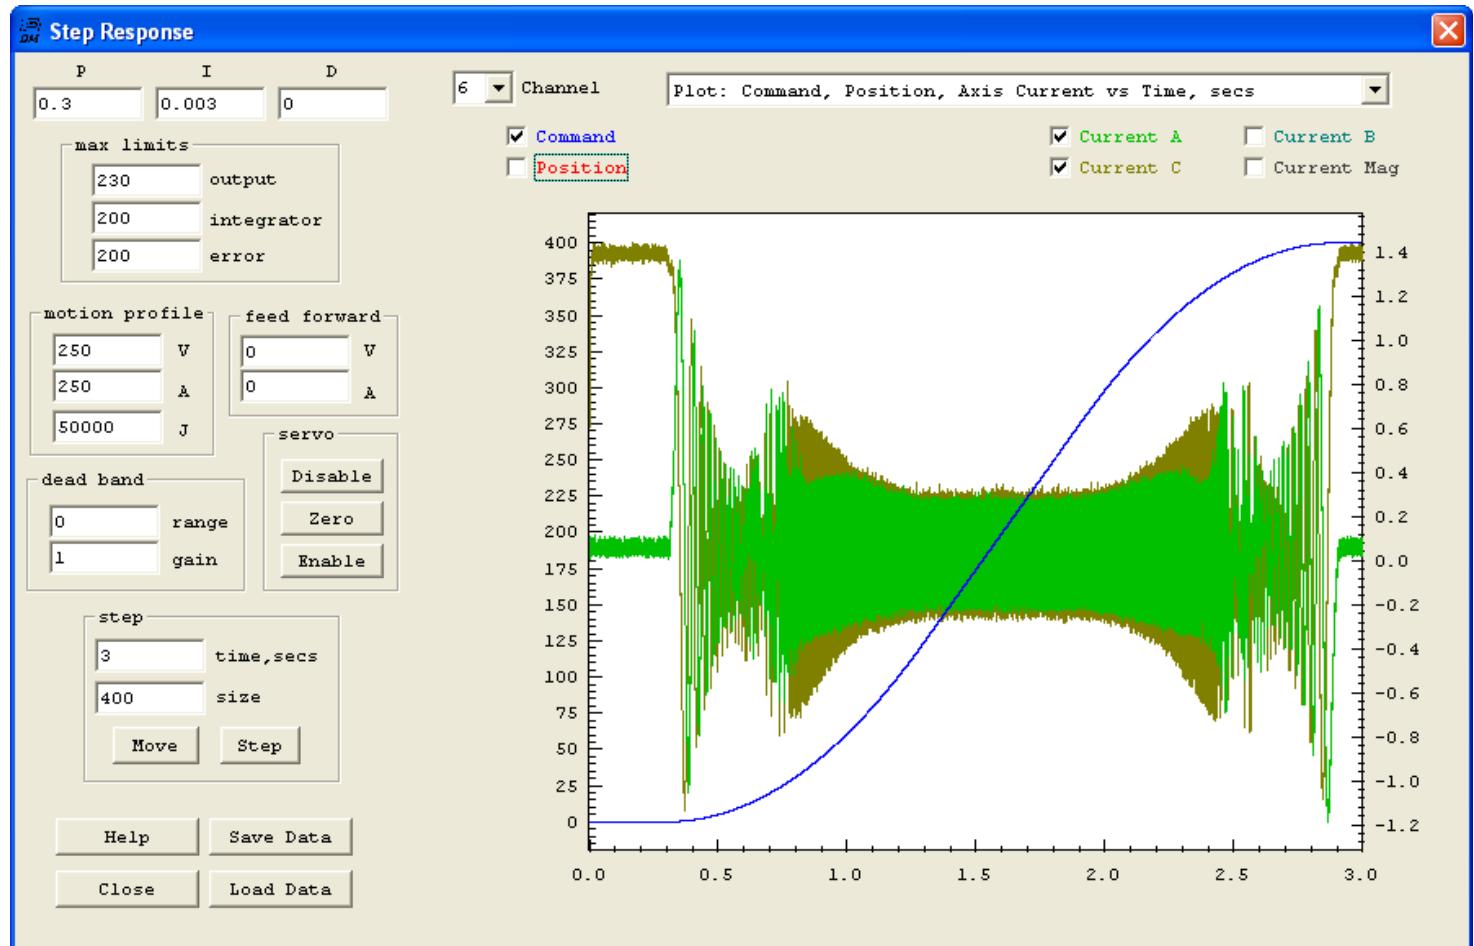

Zooming in on the current waveform at around 1 second where the motor noise seems to begin.

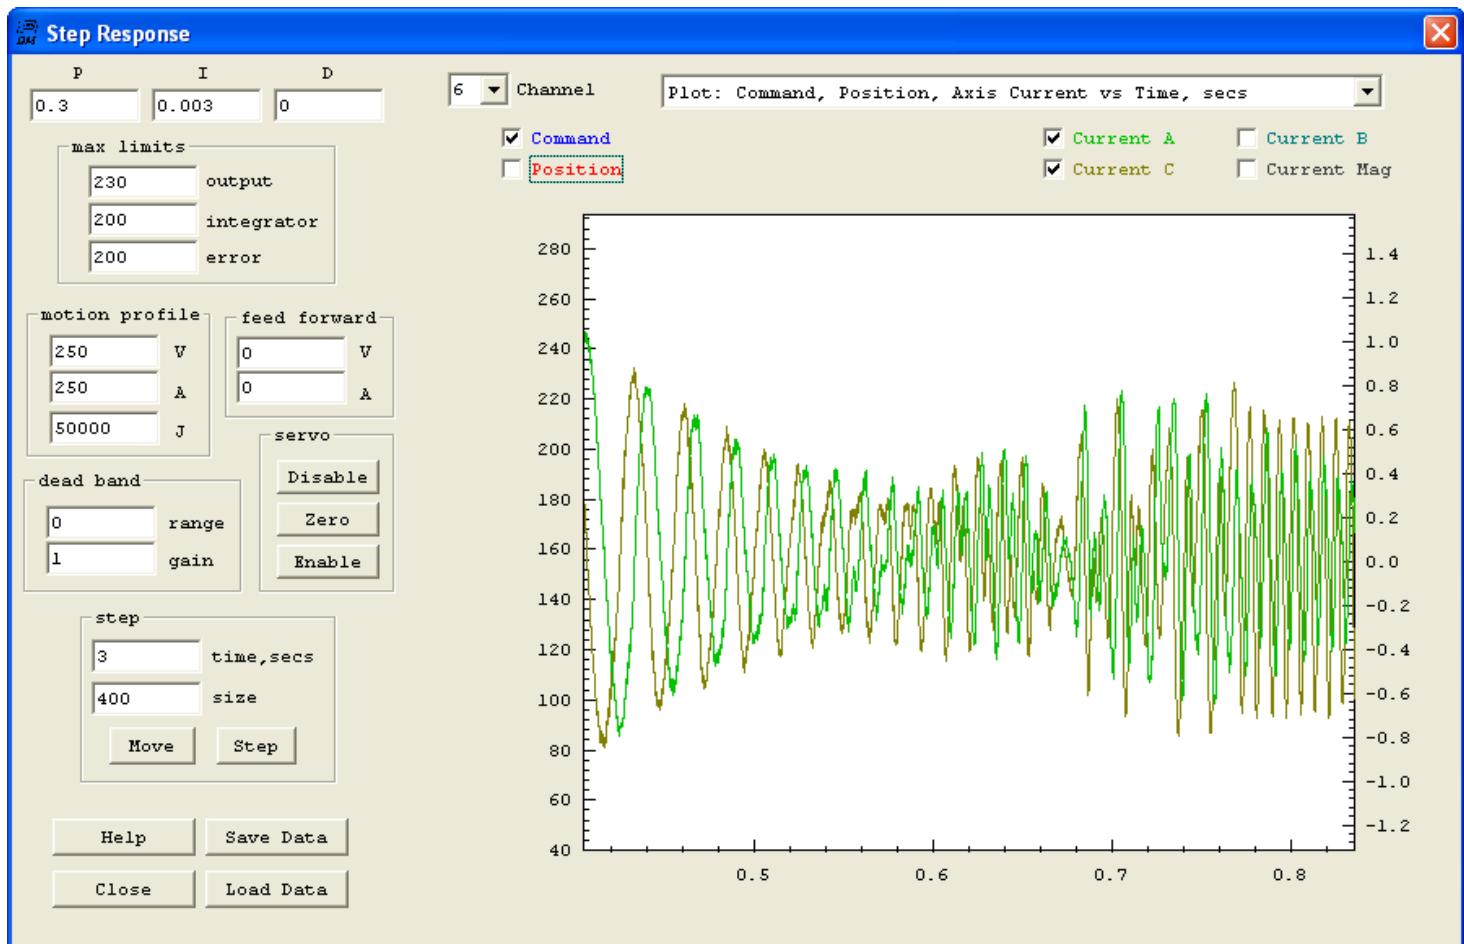

Zooming still further at 0.98 seconds where the odd behavior seems most pronounced.

## Current Waveforms with no Lead - Current drops and motor immediately stalls

Zooming in on the initial stall region

## KNozz Summary

### 3D Printer Extruder Nozzle and Part Bed Heater Interface

KNozz is the latest edition to our line-up designed to control the Nozzle Heater and Bed Heater for an Extrusion Type 3D Printer.

KNozz provides two Thermistor Inputs to allow KFLOP to monitor the temperature of both the Extruder Nozzle and Bed Heater Platform. 12-bit ADC converter provides better than 1 degree C temperature repeatability.

Two High Current, Independent, and Optically Isolated FET switches allow controlling the Nozzle and Bed Heaters. Super low on resistance of only 2.1 milli-ohms permits continuous currents of up to 20 Amps with no heat sinking required. Channels isolated from each other and may use separate supplies.

Safety Watchdog automatically disables heater outputs whenever temperatures are not being actively monitored.

An additional opto-isolated analog output is provided for general use.

3 LED status indicators for: Watchdog Enable, Nozzle Heat Powered and Driven, Bed Heat Powered and Driven,

Simple 16-pin ribbon connection to KFLOP JP4 provides logic power and data communication to/from KFLOP.

CNC Application Note: KNozz may also be used in CNC Applications to provide an isolated analog Spindle Speed Output, two isolated switches for Spindle On/Off/Direction Control, and 2 analog inputs for FRO and SSO potentiometer inputs.

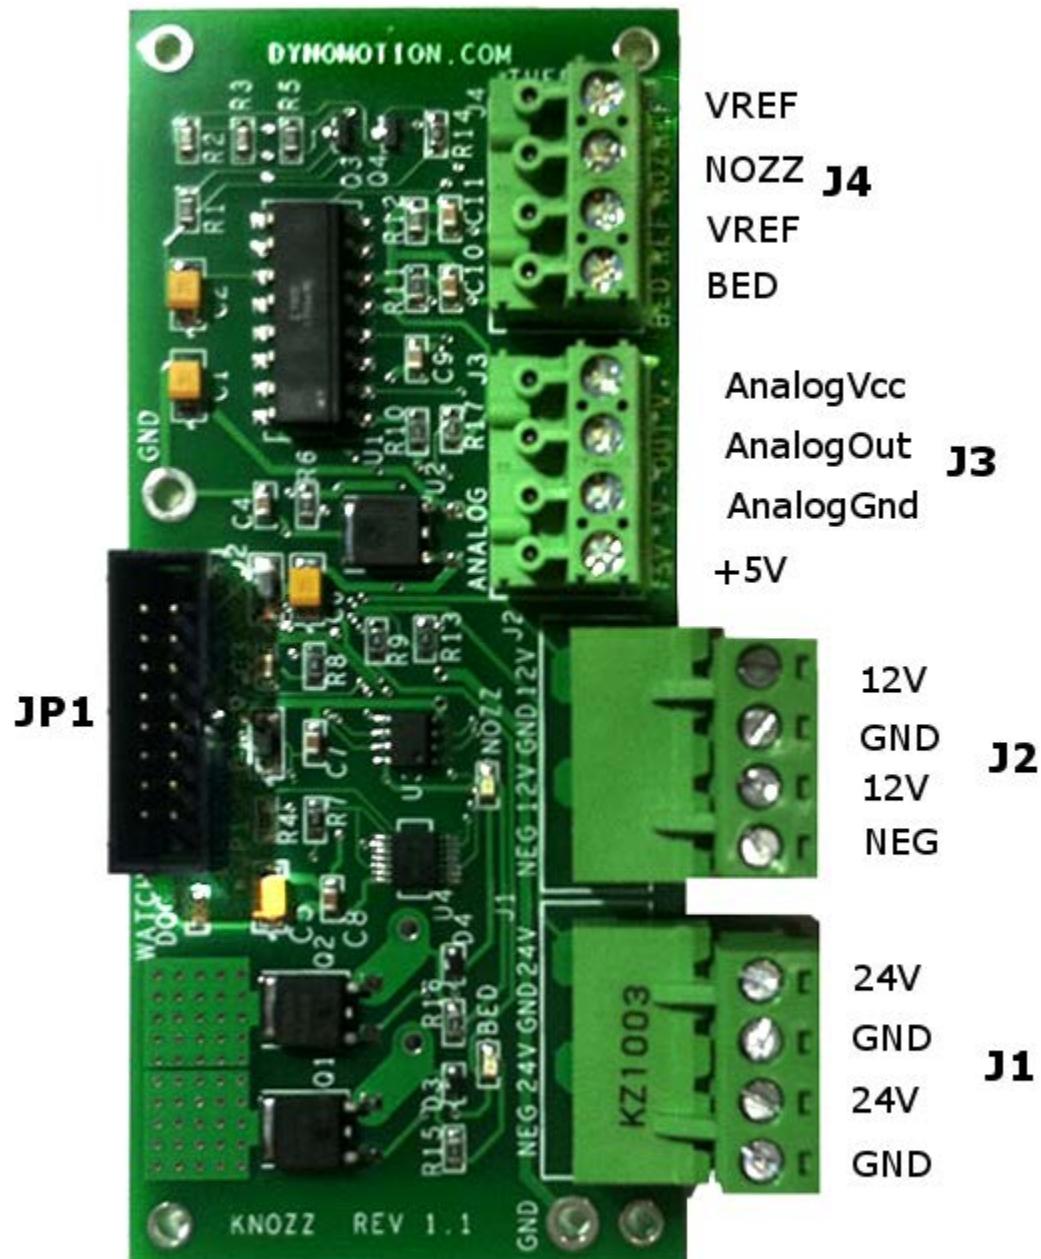

#### Features:

- ADC Nozzle Thermistor Input for Temperature Measurement
- ADC Bed Thermistor Input for Temperature Measurement
- 20Amp 48V Opto-Iso FET Switch for Nozzle Heater Element
- 20Amp 48V Opto-Iso FET Switch for Bed Heater Element
- Heaters Watch Dog
- Isolated PWM to Analog Converter
- 3 LED Status Indicators for Watch Dog, Bed, and Nozzle Heaters
- Thermistor Voltage Reference
- Direct Connection to KFLOP JP6
- Screw Terminals

## KNozz – Connector Pinouts

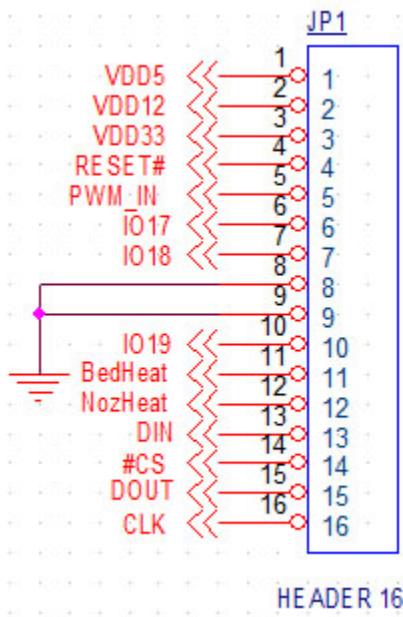

## KNozz Connection to KFLOP JP1

JP1 provides all internal signal and power connections to KFLOP. This 16 pin ribbon connection should be as short as possible to avoid noise and crosstalk as the cable forms a high speed communication link. It can be connected to either KFLOP JP4 or JP6. However for the Analog Output to be functional JP6 must be used which has KFLOP's PWM Outputs.

PWMIN is used for the isolated Analog Output. BED HEAT and NOZ Heat control the two High power FET outputs. The ADC signals are SPI signals to the dual channel ADC for reading the Thermistor Temperature readings. See KNozz C Program Examples.

Pin	KFLOP Name (JP4)	KFLOP Name (JP6)	KNozz Name
1	VDD5	VDD5	VDD5
2	VDD12	VDD12	
3	VDD33	VDD33	VDD33
4	RESET#	RESET#	
5	IO16	IO26	PWMIN

14	IO23	IO33	ADC #CS
15	IO24	IO34	ADC DOUT
16	IO25	IO35	ADC CLK

## KNozz J1 and J2 High Power FET Outputs

KNozz provides two independent opto isolated high current FET switch outputs. Although 3D Printer Bed Heaters are often driven with a 24V supply and Nozzle Heaters are often driven by a 12V supply any voltage from 12 to 48V can be applied and switched.

Connect the + Supply Voltage to Bed24V (or Noz12V) and the Supply GND to BedGND (or NozGND). Connect the Heater Element between Bed24V (or Noz12V) and the BedNeg (or NozNeg) terminals. The "Neg" terminals are driven the Supply GND when active and open circuit when inactive.

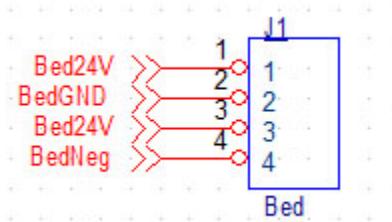

Both Outputs have an associated LED to indicate when Voltage is applied to the Output. The Output and LED will only be active when the WatchDog is active, the associated input is being driven, and a power supply is attached and providing power.

The BED HEAT (or NOZ HEAT) inputs are active high (they must be driven > 2.0V to enable the FET Outputs).

GND  
24V  
GND

**J1**

12V  
GND  
12V  
NEG

**J2**

### KNozz J3 Analog Output

KNozz provides one opto isolated Analog output. A positive isolated supply voltage should be applied across AnalogVcc and AnalogGnd. The AnalogOut voltage will then be a function of the PWM duty cycle. Note the Output is normally isolated from KFLOP GND so make sure to use the AnalogGnd as the voltage reference.

The PWM input pin is Pin5 of JP1. KFLOP JP6 Aux1 connector has PWM0 output on this pin. The AnalogOut function will only work when KNozz is connected to KFLOP JP6 Aux1.

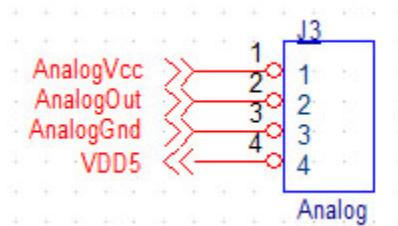

The PWM to Analog Circuit used is the same as for KStep. See the KStep documentation for more information.

See the Spindle\_S\_KNozz.c example for how to interface KMotionCNC's S command to the Analog Output.

A Terminal with +5V connected to KFLOP +5V is also provided.

AnalogVcc  
AnalogOut **J3**  
AnalogGnd  
+5V

### KNozz J4 Thermistor Analog Inputs

KNozz provides two 12-bit analog inputs normally used for Nozzle and Bed Temperature measurement. A C Program running in KFLOP is normally used to bit-bang SPI to read the ADC values, determine the temperatures, and control the Heaters. See the C Program KNozz Examples.

A single 3.3V (+/-1%) Reference is also provided that is also used for the Internal ADC Converter. Normally Thermistors used with 3D Printers change resistance from ~100K ohms at room temperature to ~5K ohms at build temperature. The external Thermister should be connected between the VREF terminal and the NOZZ (or BED) Terminals.

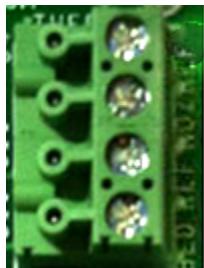

A Thermistor and internal 10K ohm (+/- 1%) resistor form a Voltage divider. See the circuit below.

The relationship between input Voltage to ADC reading in counts is:

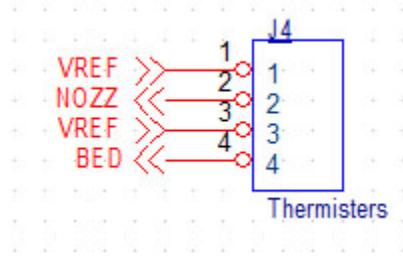

$$ADC = 4097 \times Vin / VREF$$

The relationship between resistance R and ADC reading in counts is:

$$ADC = 4097 \times 10K / (10K + R)$$

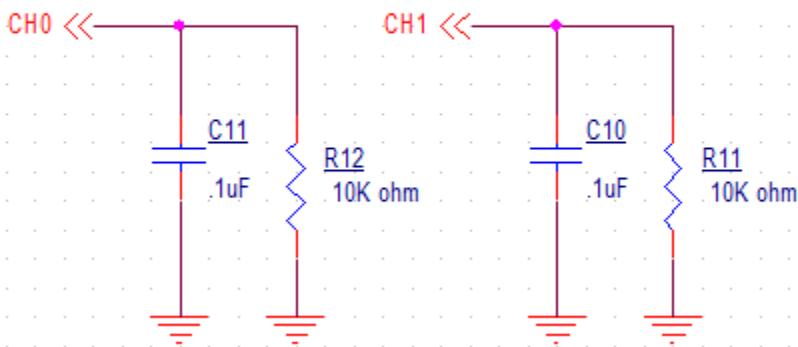

VREF  
NOZZ J4  
VREF  
BED

Each Thermistor input circuit includes a filter capacitor ( $0.1\mu F$ ) that will slow response and reduce noise. The response time will change depending how the input is driven but at high resistance the input response will be:

$$\Tau = RC = 10K \times 0.1\mu F = 1ms$$

The Thermistor drops from about 100Kohms at room temperature to about 5Kohms at build temperature.

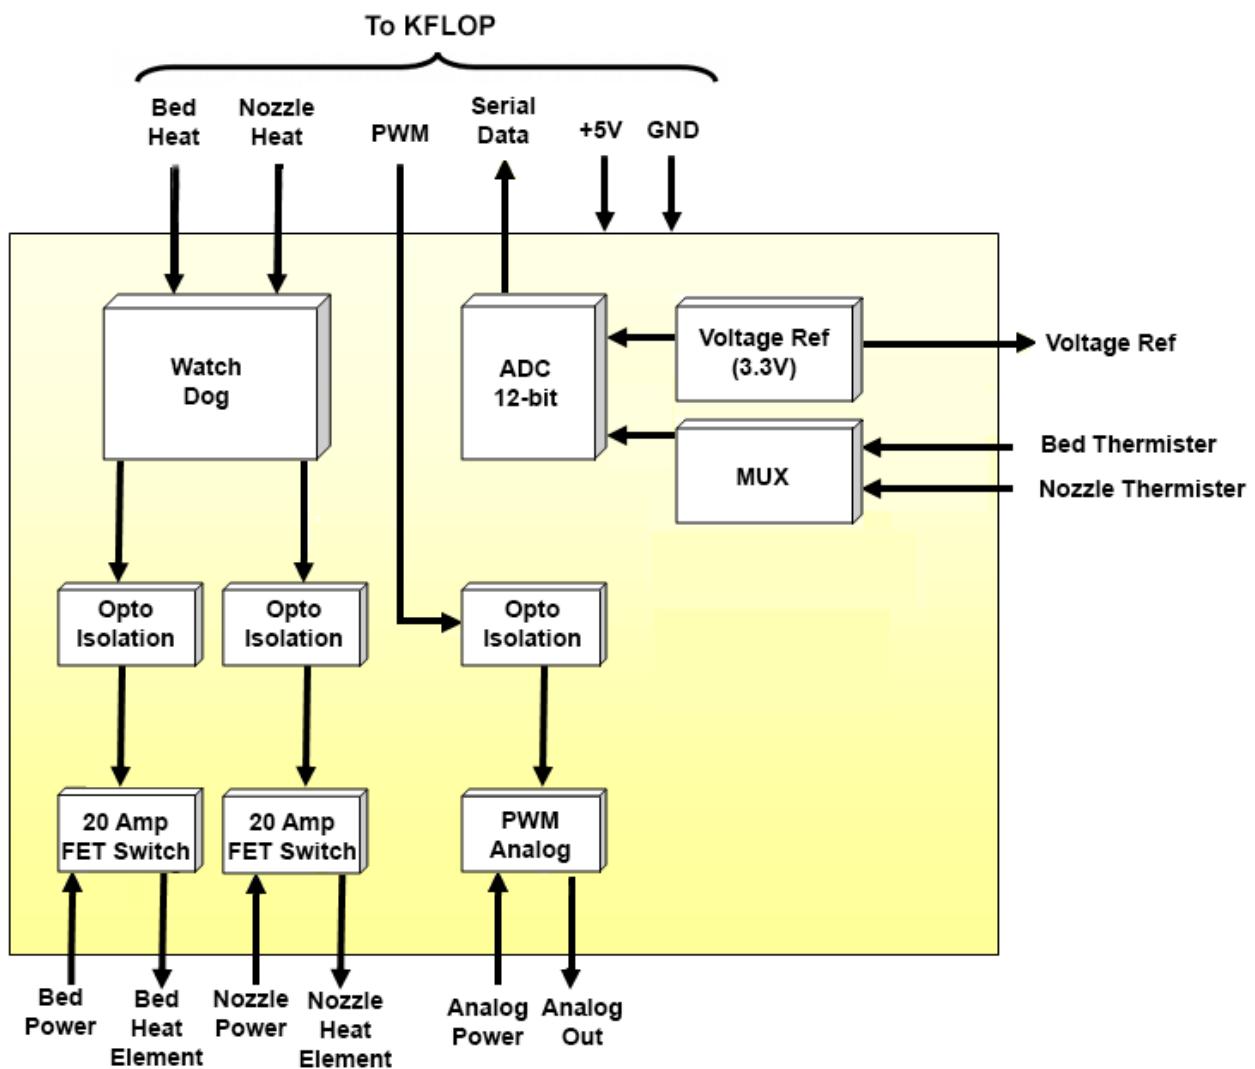

## WatchDog

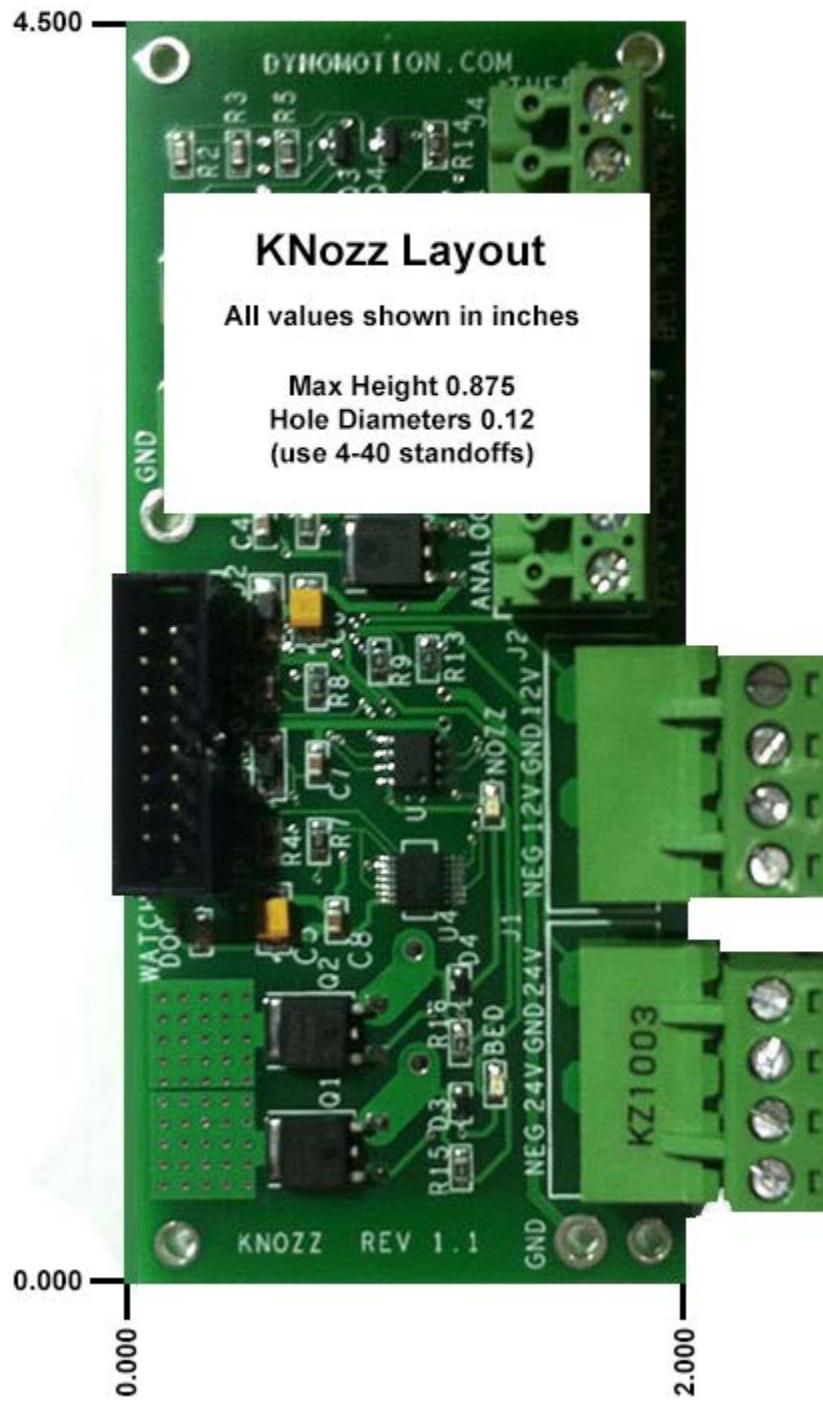

KNozz includes a WatchDog Circuit to help avoid thermal runaway of the Heaters if the FET Outputs are somehow turned on while the temperatures are not being actively monitored. To read the temperatures the ADC CLK input must be toggled. If the ADC Clock stops toggling, then the WatchDog Circuit trips and disables both FET Outputs after approximately 3ms. The WatchDog LED illuminates when the ADC Clock is toggling and the Outputs are enabled to be turned on.

## KNozz Block Diagram

# KNozz Block Diagram

## KNozz Board Layout

## Configuring Step and Direction Outputs

KFLOP supports connection to motor amplifiers that utilize step and direction (or [quadrature](#)) inputs to control the motion. Step and direction motor amplifiers are typically used with stepper motors with or without micro-stepping capability. Each "step" causes the motor amplifier to advance the motor position one step in the direction specified by the "Direction" signal. Only two digital output signals are required for this interface. Fine micro-stepping resolution combined with high motor RPM can result in step rates in the megahertz. For example, a 200 step/rev stepping motor with 128:1 micro-stepping running at 3000 RPM requires:

$$3000 \text{ RPM} / 60 \text{ Sec/Min} * 200 \text{ steps/rev} * 128 \mu\text{steps/full step} = 1.28 \text{ MHz } \mu\text{steps/sec}$$

KFLOP has 8 axes of Step and Direction. Output pulses up to 2.5 MHz can be generated.

The 8 Axes of Step/Dir outputs are normally hard wired to IO bits 8 through 15 on JP7 and IO bits 36 through 43 on JP5. However the first 4 Step/Dir outputs can be multiplexed to connectors JP4 and JP6 if desired. This may be required if JP7 is used for some other purpose such as interfacing to the Kanalog I/O Expander. A global [multiplexing bit](#) is used to switch the outputs to the alternate connectors.

Note that the first 8 of 10 I/O pins of Aux #0 and Aux #1 have internal 150 Ohm pull down resistors. Therefore Pins JP4-13, JP4-14, JP6-13 and JP6-14 may not be used in Open Collector mode.

If an axis channel is selected as a Step and Direction axis, the corresponding 2 output pins will be automatically configured as outputs and they may not be used as general purpose IO.

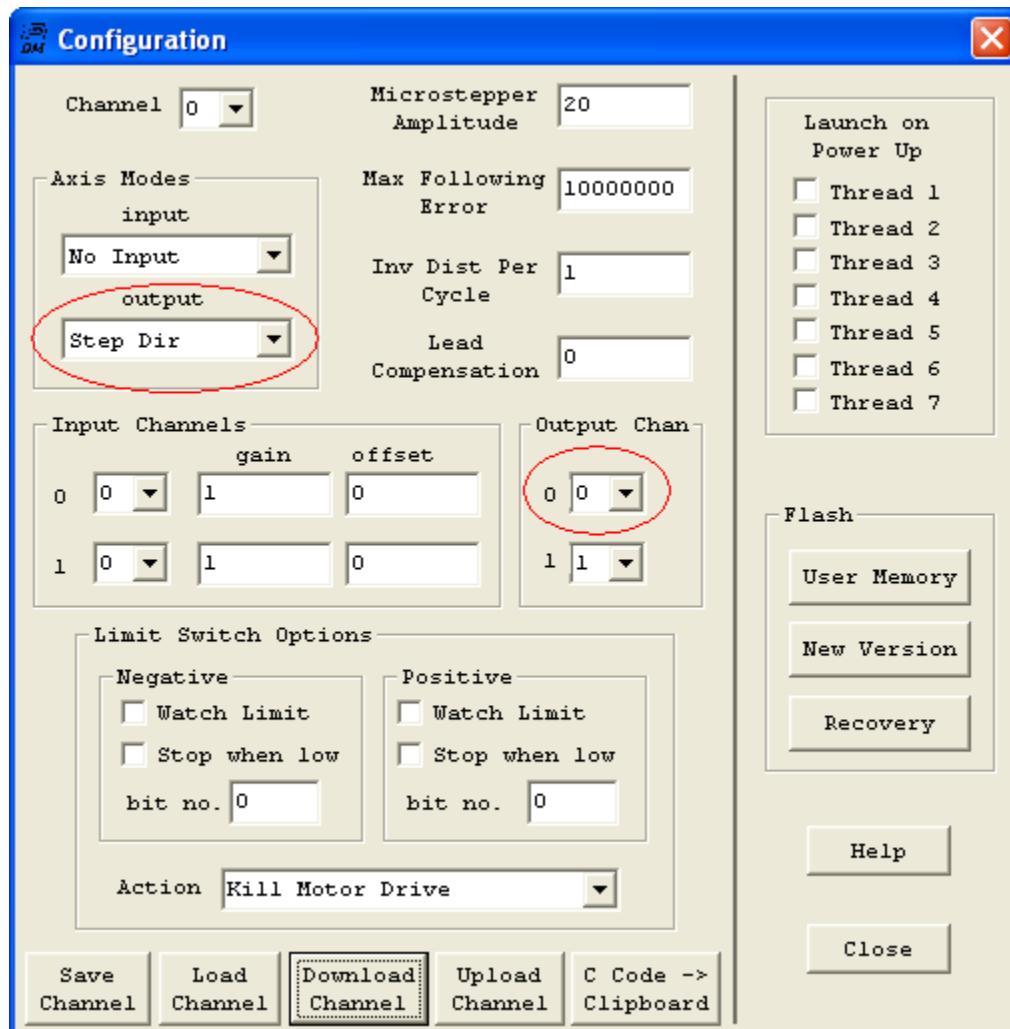

For KFLOP see the Table below:

	Mux = 0		Mux = 1	
Signal	IO Bit	Pin	IO Bit	Pin
Step 0	8	JP7 - 15	22	JP4 - 13
Direction 0	9	JP7 - 16	23	JP4 - 14
Step 1	10	JP7 - 17	24	JP4 - 15
Direction 1	11	JP7 - 18	25	JP4 - 16
Step 2	12	JP7 - 19	32	JP6 - 13
Direction 2	13	JP7 - 20	33	JP6 - 14
Step 3	14	JP7 - 21	34	JP6 - 15
Direction 3	15	JP7 - 22	35	JP6 - 16

Signal	IO Bit	JP5 Pin
Step 4	36	JP5 - 1
Direction 4	37	JP5 - 2
Step 5	38	JP5 - 3
Direction 5	39	JP5 - 4
Step 6	40	JP5 - 5
Direction 6	41	JP5 - 6
Step 7	42	JP5 - 7
Direction 7	43	JP5 - 8

To configure an axis as step and direction, on the Configuration Screen select output mode as "Step Dir" and select which of the 4 available Step and Direction generators should be used by setting the appropriate Output Channel 0 setting. See below.

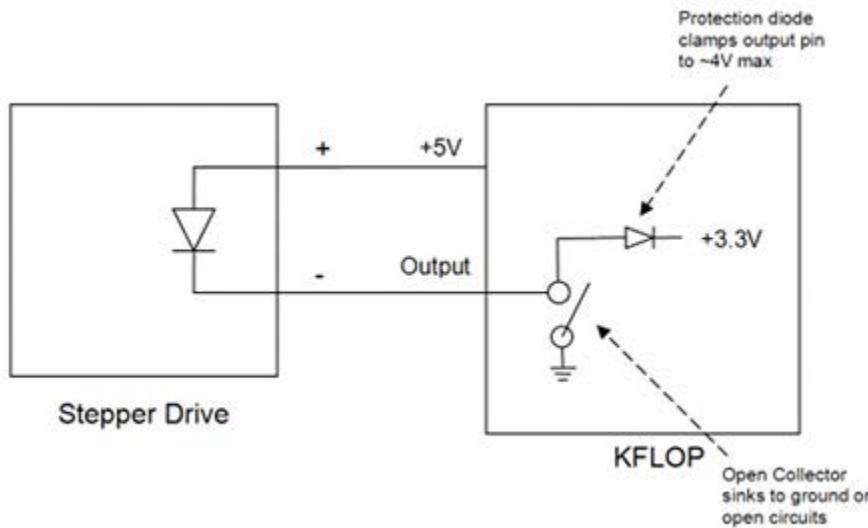

Valid output channel settings 0-31 are allowed for KFLOP. Although only 8 Step and Direction generators are available for KFLOP by adding 8 and/or 16 to the channel number the mode of the Step/Dir Generator can be changed.

Adding 8 to the channel number uses the same generator to be used except the output pins are actively driven (high and low) as 3.3V LVTTL signals instead of only driven low as open collector outputs.

Adding 16 to the channel number switches the generator from Step/Dir to Quadrature output mode.

If your amplifier has opto coupler inputs driven off +5V then open-collector mode is likely to work better. The diagram below shows how the open collector mode works driving the LED of an Opto Coupler with the anode connected to +5V.

However if the amplifier has standard logic inputs then LVTTL outputs should work better.

Quadrature outputs are required for some amplifiers. Quadrature outputs output two A B phases instead of Step/Dir signals. An advantage is that only one signal edge transition takes place for each "step" as opposed to a complete pulse.

The table below summarizes the modes:

Output Chan 0 Setting	Step & Dir Generator Selected	Output Drive Type
0	0	Open Collector - Step/Dir
1	1	Open Collector - Step/Dir
2	2	Open Collector - Step/Dir
3	3	Open Collector - Step/Dir
4	4	Open Collector - Step/Dir
5	5	Open Collector - Step/Dir
6	6	Open Collector - Step/Dir
7	7	Open Collector - Step/Dir
8	0	LVTTL - Step/Dir
9	1	LVTTL - Step/Dir
10	2	LVTTL - Step/Dir
11	3	LVTTL - Step/Dir
12	4	LVTTL - Step/Dir
13	5	LVTTL - Step/Dir
14	6	LVTTL - Step/Dir
15	7	LVTTL - Step/Dir

16	0	Open Collector - Quadrature
17	1	Open Collector - Quadrature
18	2	Open Collector - Quadrature
19	3	Open Collector - Quadrature
20	4	Open Collector - Quadrature
21	5	Open Collector - Quadrature
22	6	Open Collector - Quadrature
23	7	Open Collector - Quadrature
24	0	LVTTL - Quadrature
25	1	LVTTL - Quadrature
26	2	LVTTL - Quadrature
27	3	LVTTL - Quadrature
28	4	LVTTL - Quadrature
29	5	LVTTL - Quadrature
30	6	LVTTL - Quadrature
31	7	LVTTL - Quadrature

Note when configuring the motion profile for a Step and Direction Axis the appropriate maximum Velocity, Acceleration, and Jerk should be set in units of micro-steps/sec, micro-steps/sec<sup>2</sup>, and micro-steps/sec<sup>3</sup> respectively.

## **Global Register sets Pulse Width, Polarity, Multiplexor**

To change the Step/Dir Pulse width, Step Pulse Polarity, and connector multiplexor for channels 0-4 a programmable register in KFLOP's FPGA may be used.

KFLOP has the capability to program the Step pulse width as a 6-bit value. The default setting is 2us. The pulse length may be adjusted from 1 to 63 of 16.67 MHz clocks. Which corresponds to 60ns to 3.78us. Using a long pulse length limits the maximum frequency that can be generated. For example with the default pulse length of 2us the frequency should not exceed  $1/(2 \times 2\text{us}) = 250\text{KHz}$ .

Setting Bit-6 high of the register can be set high to multiplex Step/Dir generators 0-3 from JP7 to JP4 and JP6.

Setting Bit-7 high will invert the Step Output pulse so that it pulses High rather than Low. Some Amplifiers (Geckos) prefer this mode. If the drive "steps" on the falling edge of the pulse, then this option will provide more setup time for the Direction Signal. A User C Program must be used to change the FPGA register. The following statement should be used:

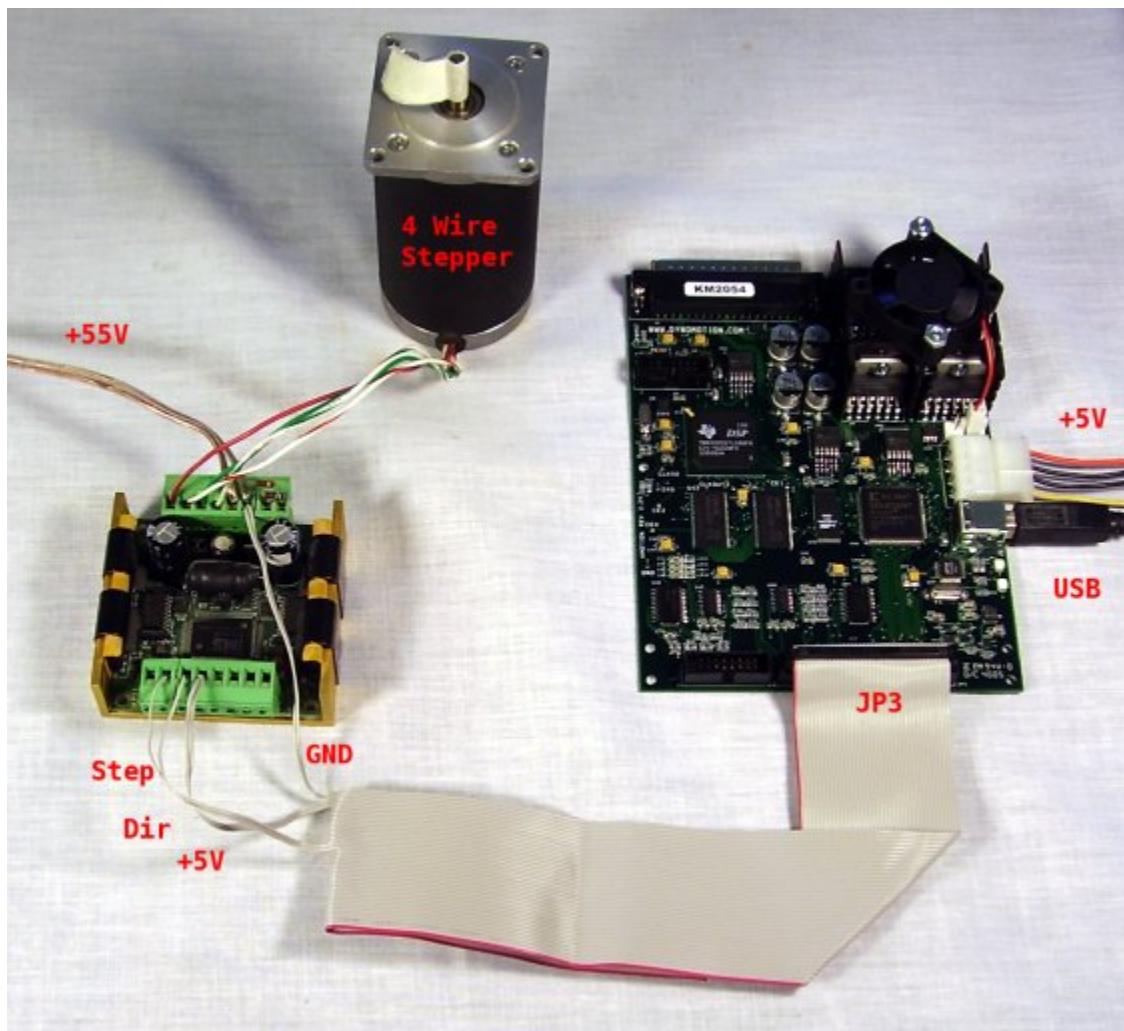

```
FPGA(STEP_PULSE_LENGTH_ADD)=32; // set the pulse time to ~ 2us
```

```
FPGA(STEP_PULSE_LENGTH_ADD)=32 + 0x40; // set the pulse time to ~ 2us and multiplex to JP4 and JP6
```

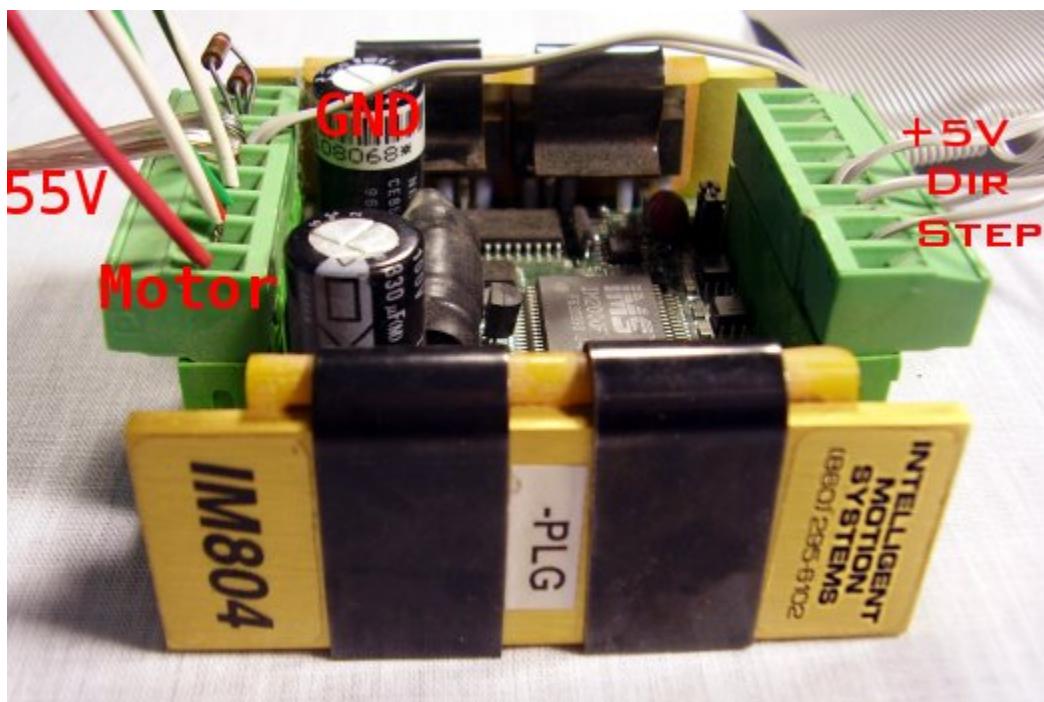

```
FPGA(STEP_PULSE_LENGTH_ADD)=32 + 0x80; // set the pulse time to ~ 2us and pulse the Step High
```

```
FPGA(STEP_PULSE_LENGTH_ADD)=32 + 0x40 + 0x80 // set the pulse time to ~ 2us, mux to JP4 and JP6, and pulse the Step High
```

## ***Example Configuration for an IM804 Amplifier and Rapidsyn Stepper***

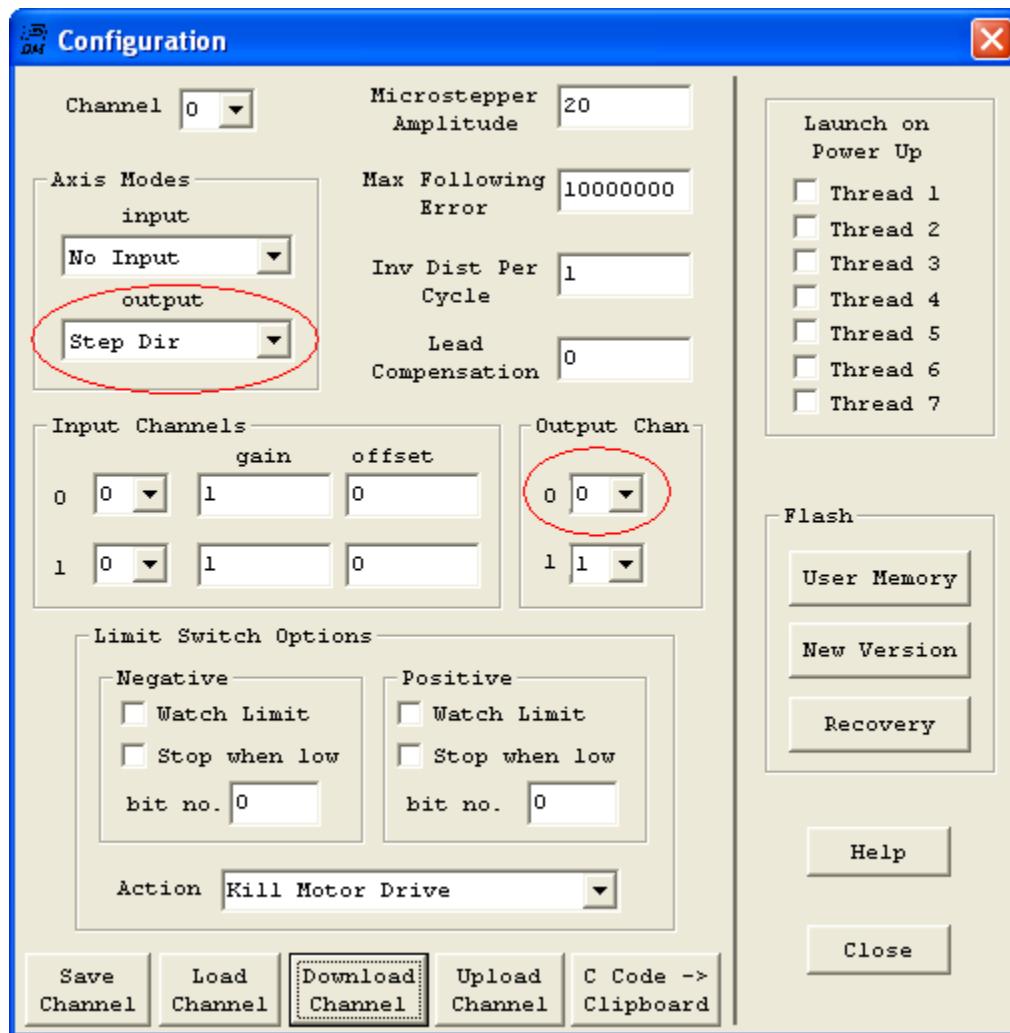

***Layout - KMotion - Amplifier - Motor***

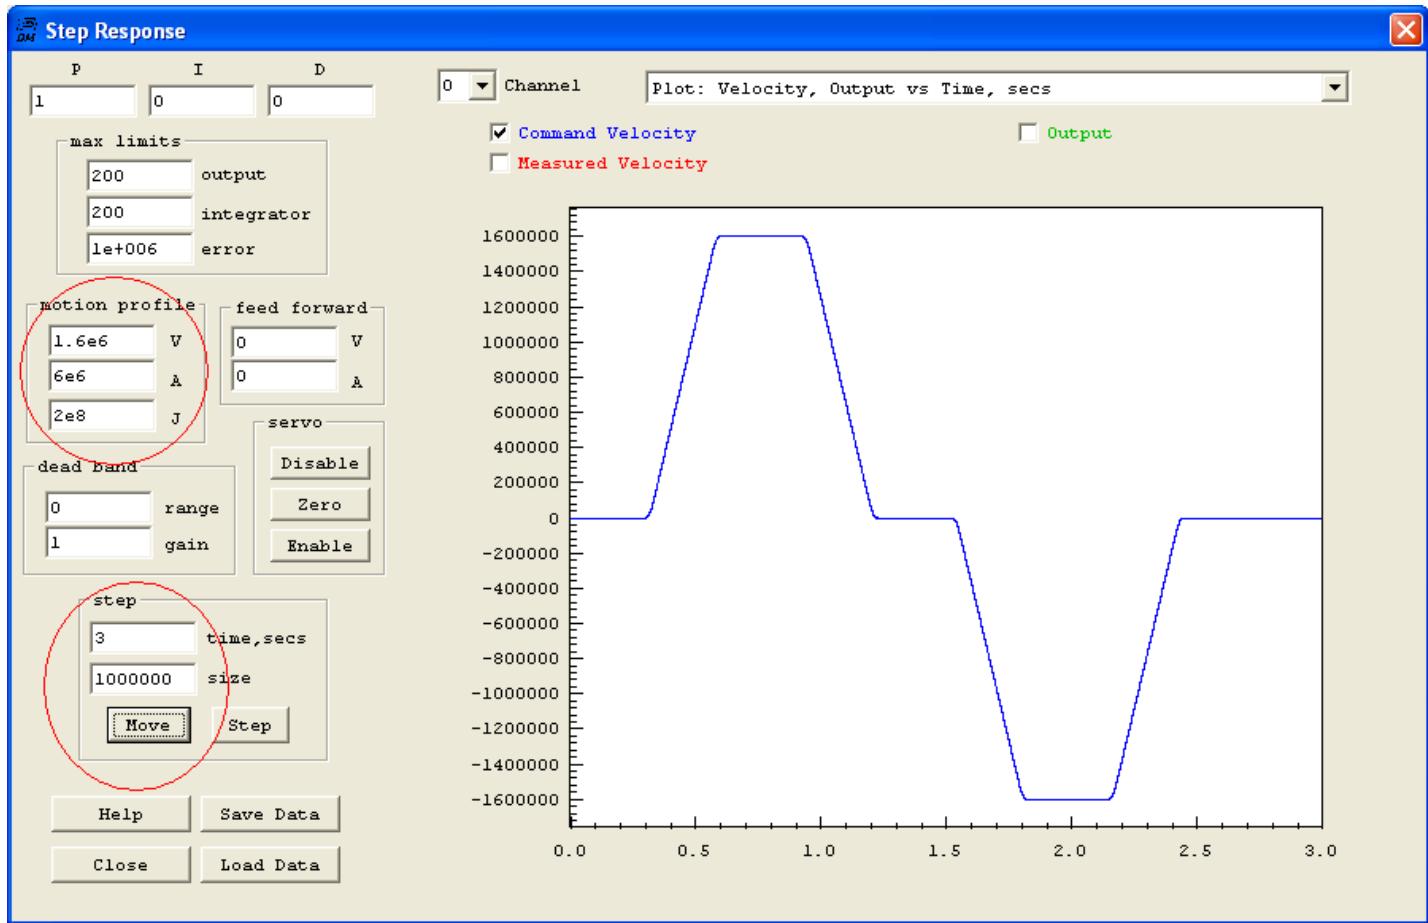

Amplifier Connections - resistors set coil currents (1500 ohms = 3A) and idle standby current (270 ohms = 0.5A). DIP Switches set to ON-OFF-OFF-ON for 128:1 micro-stepping.

Rapidsyn stepper motor. Note coil winding's centertaps are not used.

Axis channel 0 configures as "Step Dir" mode and using Step and Direction generator 0.

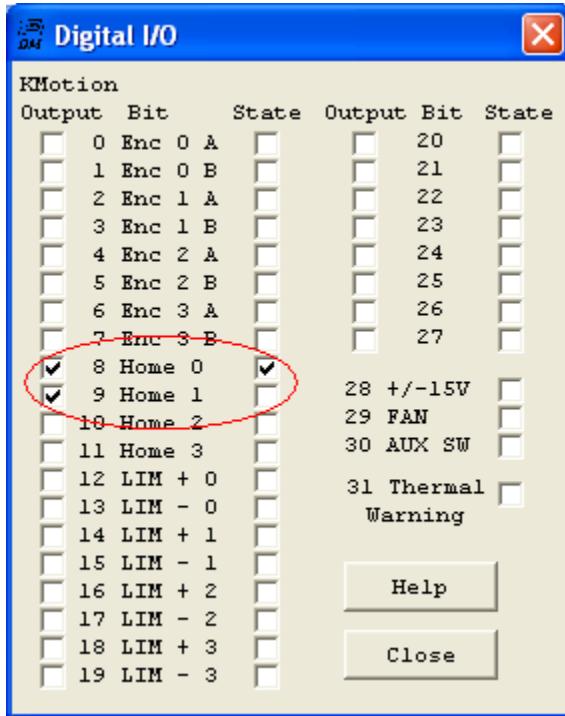

Max Velocity  $1.6 \times 10^6$  steps/sec ( $1.6e6 / 128 = 12,500$  sps = 3750 RPM). Note this (and most) steppers lose most all of their useful torque above several thousand full steps per second. The high speed demonstrated here is intended to demonstrate KMotion's ability to generate high pulse rates.

Max Acceleration  $6 \times 10^6$  steps/sec<sup>2</sup>

Max Jerk  $2 \times 10^8$  steps/sec<sup>3</sup>

$1 \times 10^6$  count Move performed and data captured over 3 seconds.

Pushing Move downloads all parameters, enables the axis, performs the movement, and plots the result.

Note after the axis has been enabled, digital IO bits 8 and 9 have automatically been configured as outputs for use by Step and Direction Generator #0.

## See Video

Click [here](#) for a video showing slow and smooth acceleration of this configuration up to 12,500 full steps per second (1.6 MHz @ 128 microsteps/full step).

## **Configuring DC Brush Motor with SnapAmp and Single-Ended Encoder to KMotion**

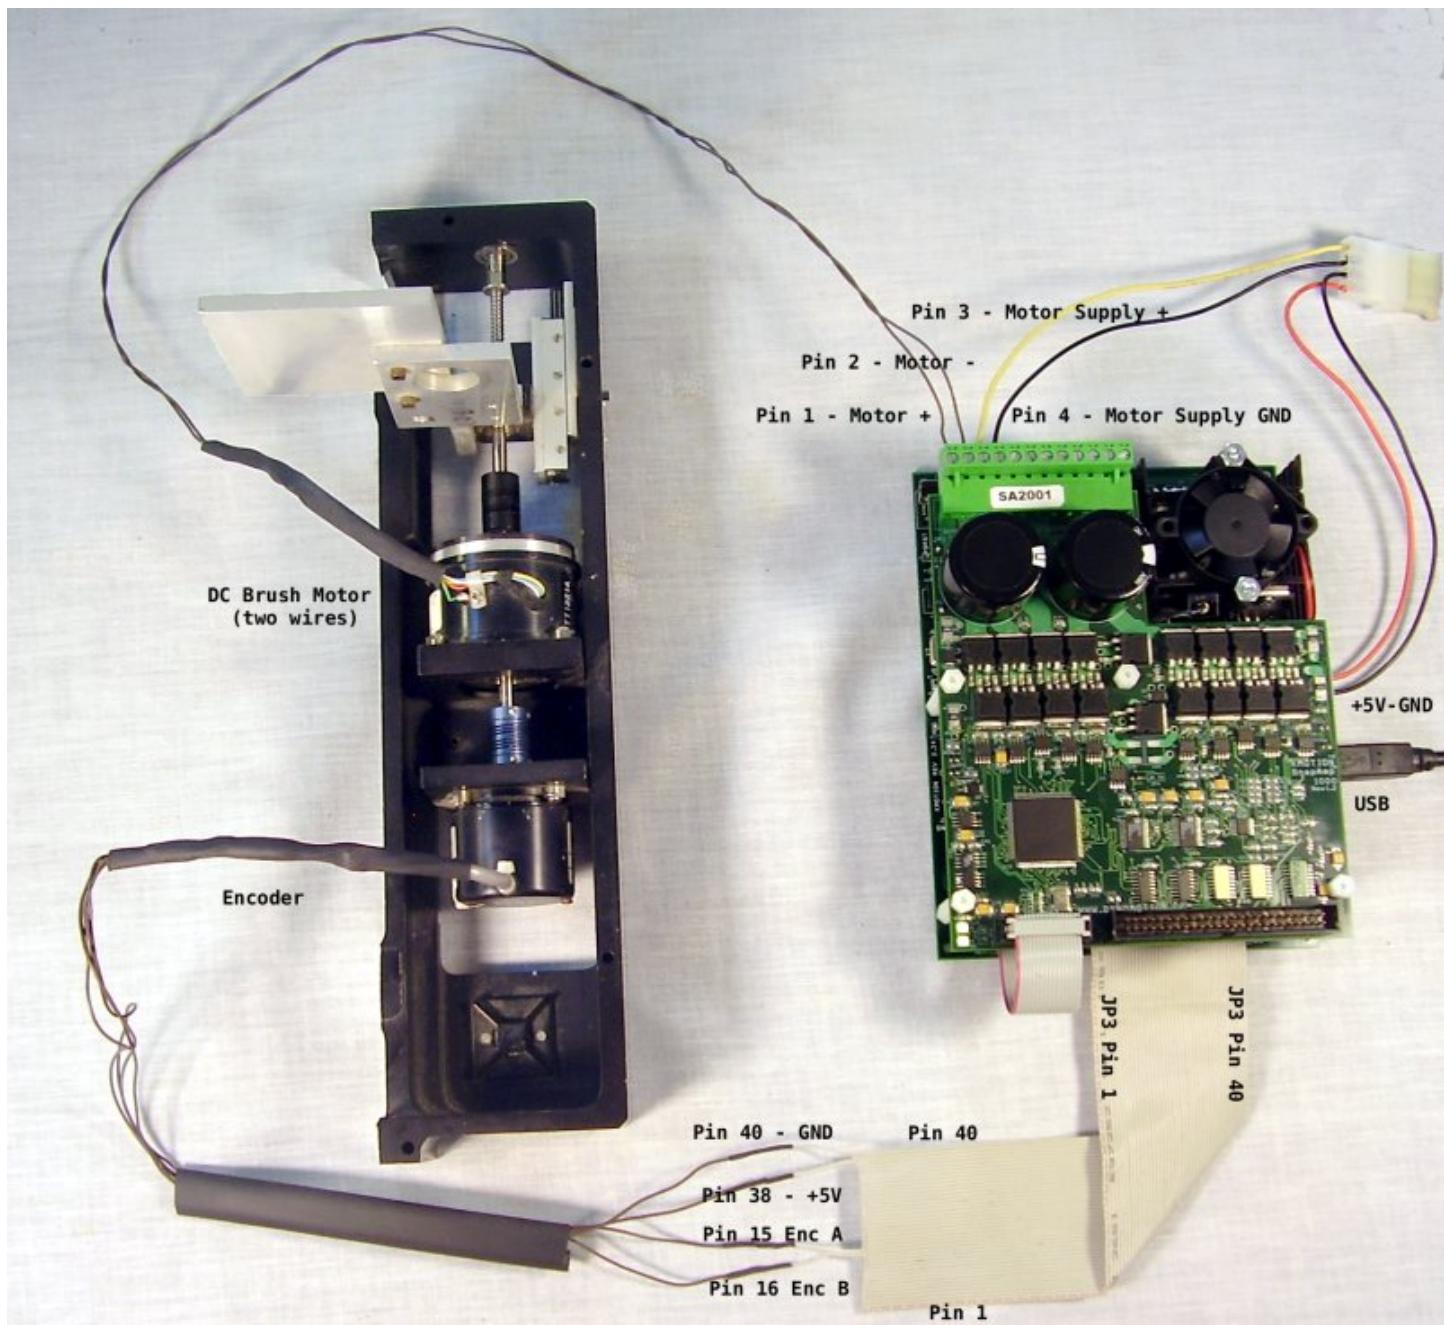

This example will proceed through the following steps

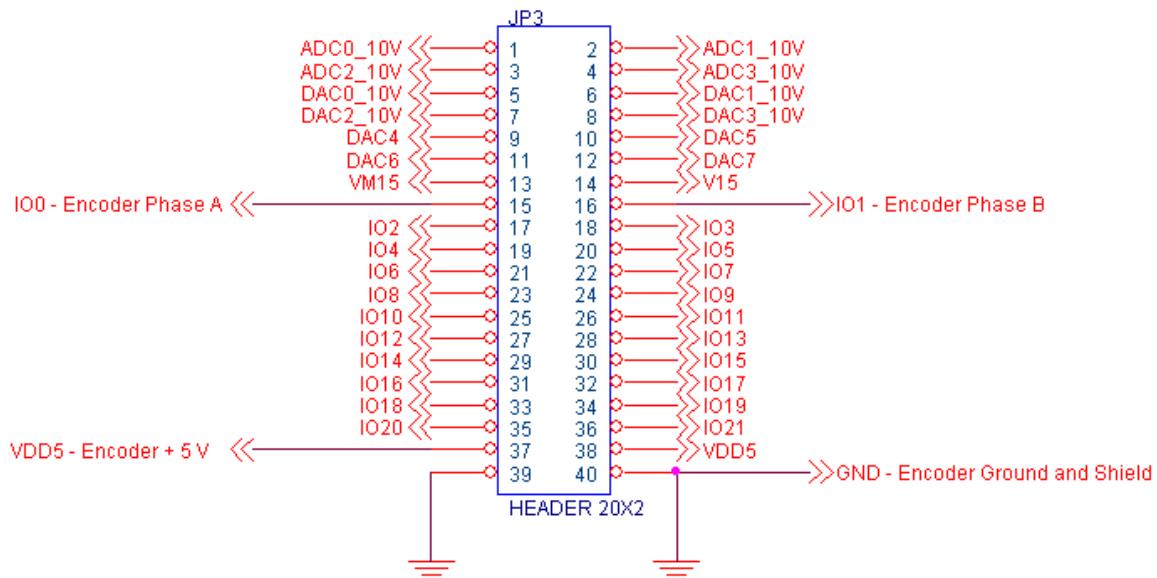

1. [Wiring the Motor, encoder, and Power](#)
2. [Configuring the Software](#)
3. [Testing the encoder](#)
4. [Testing the Motor/Amplifier](#)
5. [Closing the loop](#)
6. [Tuning the Servo](#)
7. [Executing a simple C Program Motion Sequence](#)

[Here is a video overview.](#)

### **Wiring the Motor, encoder, and Power**

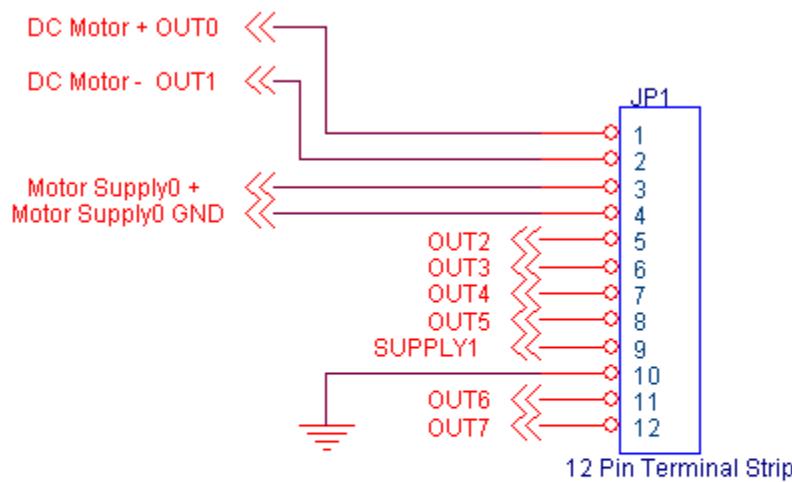

This example configuration shows a single dc brush motor connected to the first of 4 available full bridge drivers on a single SnapAmp 1000. A single-ended encoder is connected to KMotion's JP3 connector as encoder input #0 for Servo feedback. (The KMotion board is hidden underneath the SnapAmp in the photo). Note: Encoders typically come as one of two types - differential outputs (having A+, A-, B+, B-) or single ended outputs (A B). A differential encoder may be used as a single ended encoder by only using the A+ and B+ signals (and leaving the A- and B- unconnected). However single ended signals are more susceptible to noise than differential signals. KMotion has 4 single ended encoder inputs. SnapAmp 1000 has 4 differential encoder inputs. In this example a KMotion single-ended encoder input is used. Some encoders have a index pulse that occurs once per revolution usually labeled as channel Z. In this example the index is not used and is not connected.

Encoder Channel 0 Wiring Diagram

KMotion to Single Ended Encoder

SnapAmp Wiring Diagram

PWM Channel 8 to DC Brush Motor

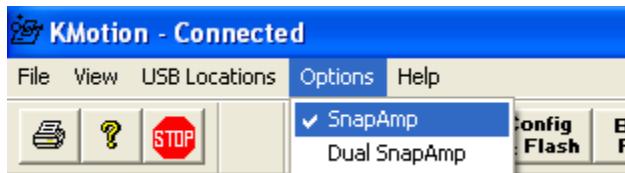

## Configuring the Software

After the motor and encoder connections have been made, the software is configured and the encoder feedback and motor is tested.

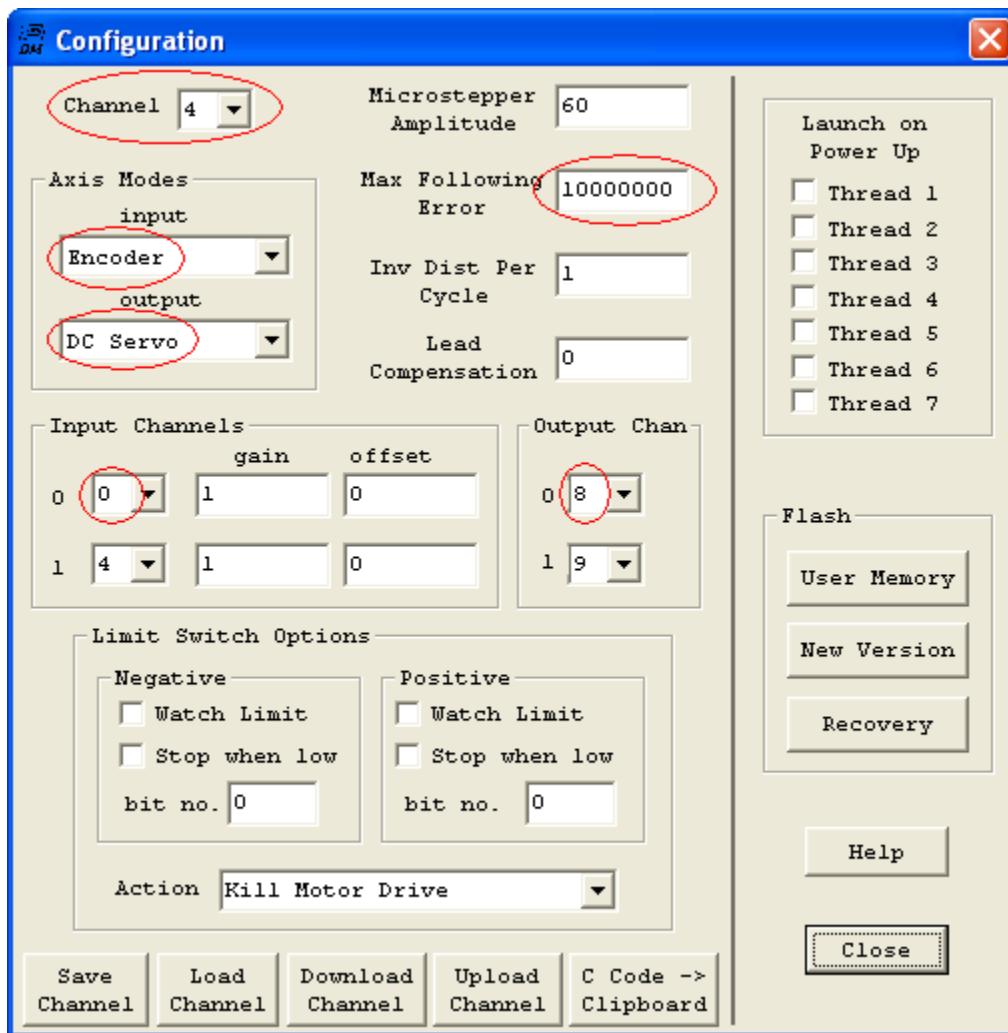

Although any of KMotion's 8 axes could be used, axis 4 will be configured since axes 0-3 are normally used for KMotion's on-board amplifiers.

In the KMotion Executive program three screens involve setting an axis's configuration: The Configuration Screen, the Step Response Screen, and the Filters Screen. These three screens and our choice of initial settings are shown below:

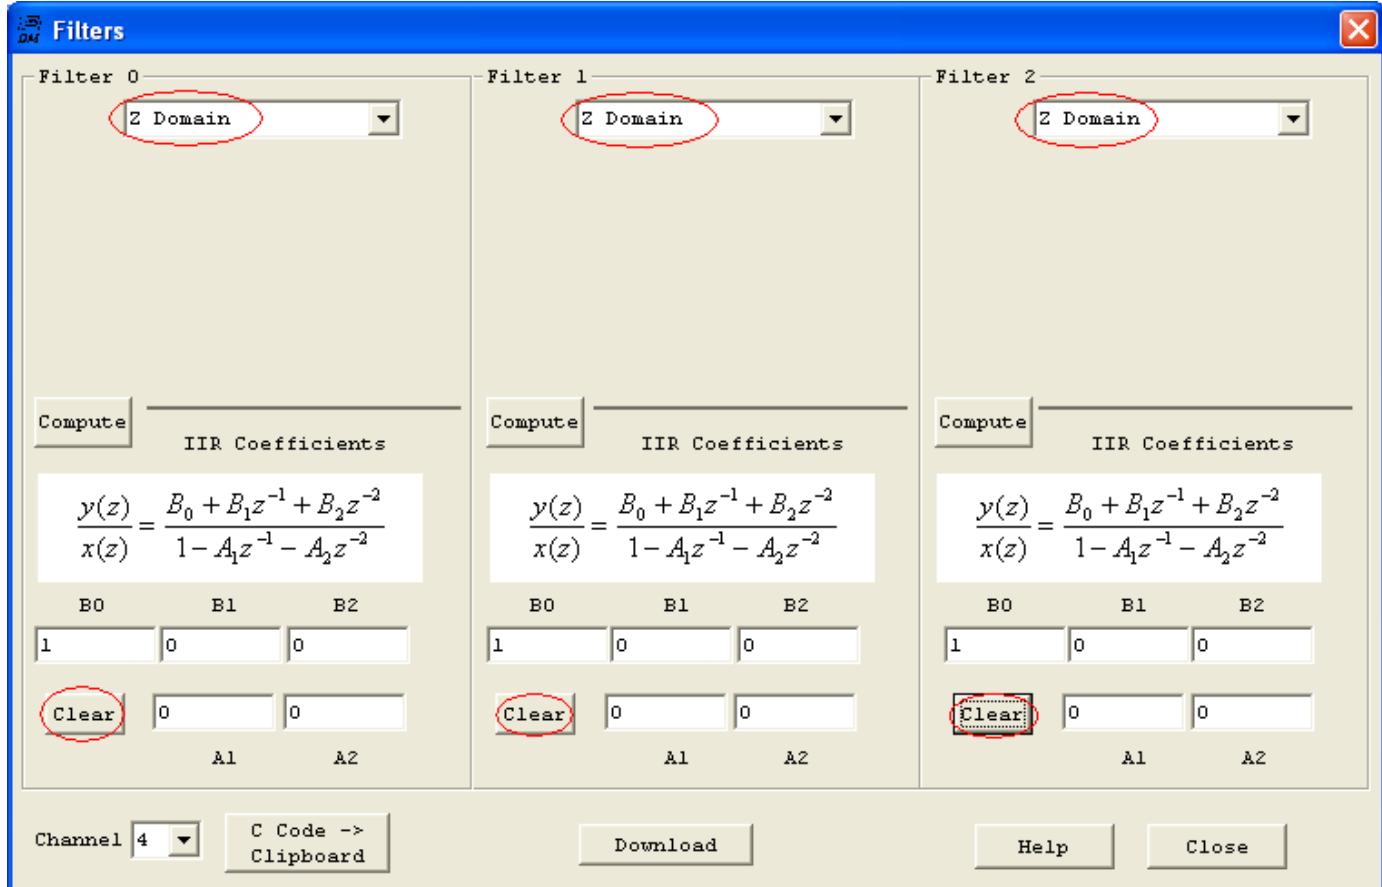

Execute the KMotion executive program and set the Options for a single SnapAmp. See below:

On the Configuration screen Axis Channel 4 is selected, the input type is set to Encoder at encoder channel 0, the output type is set to DC Servo at PWM channel 8, and a very large following error is set.

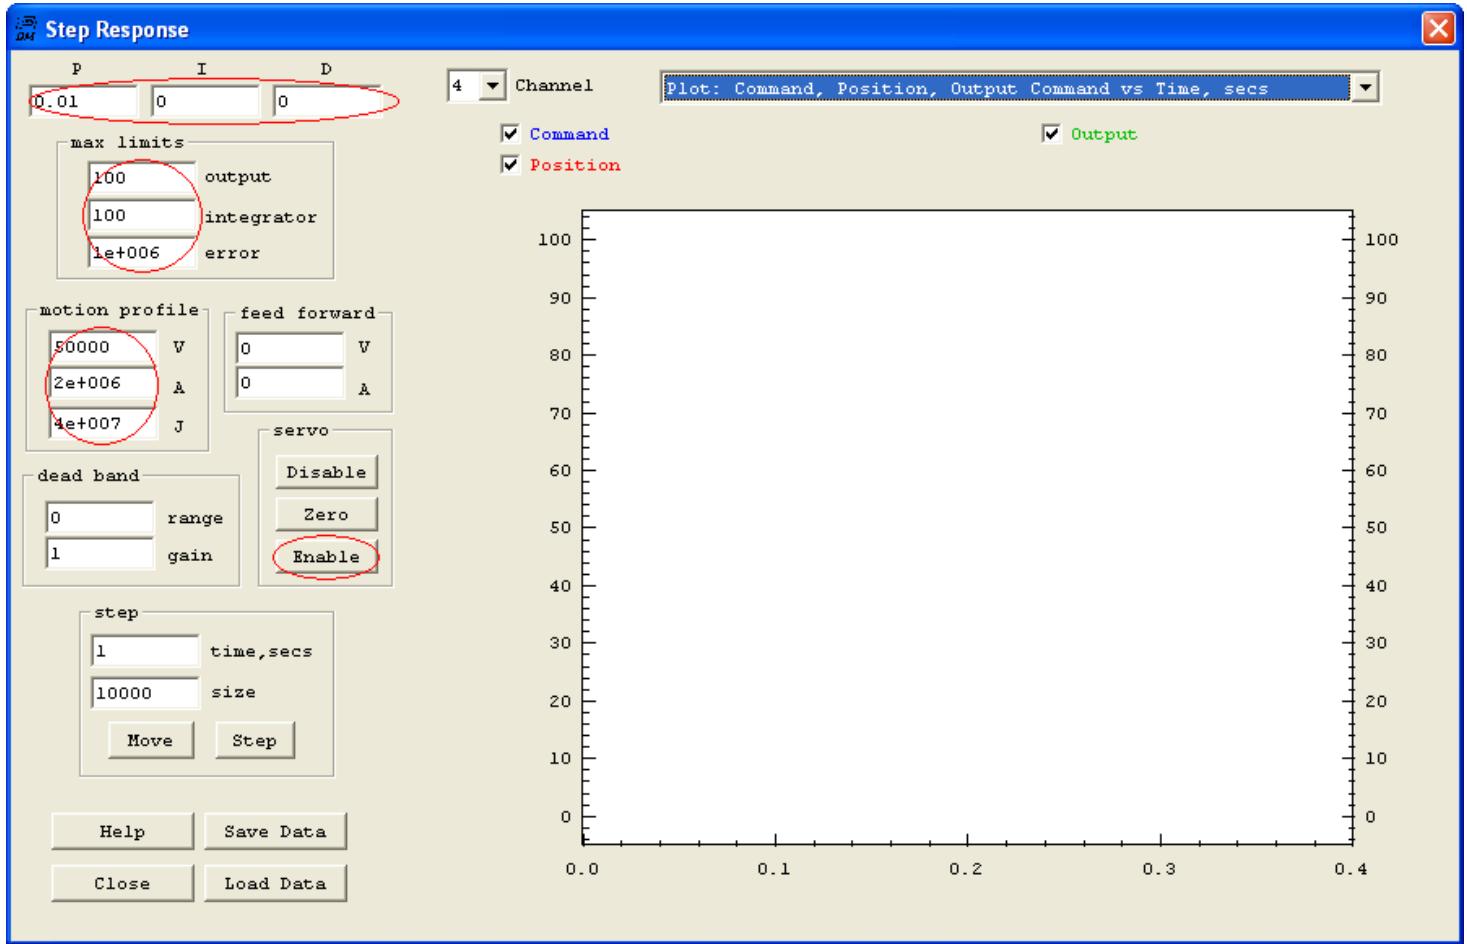

On the Filters Screen all filters are disabled by "Clearing" all filters to have a gain of 1.

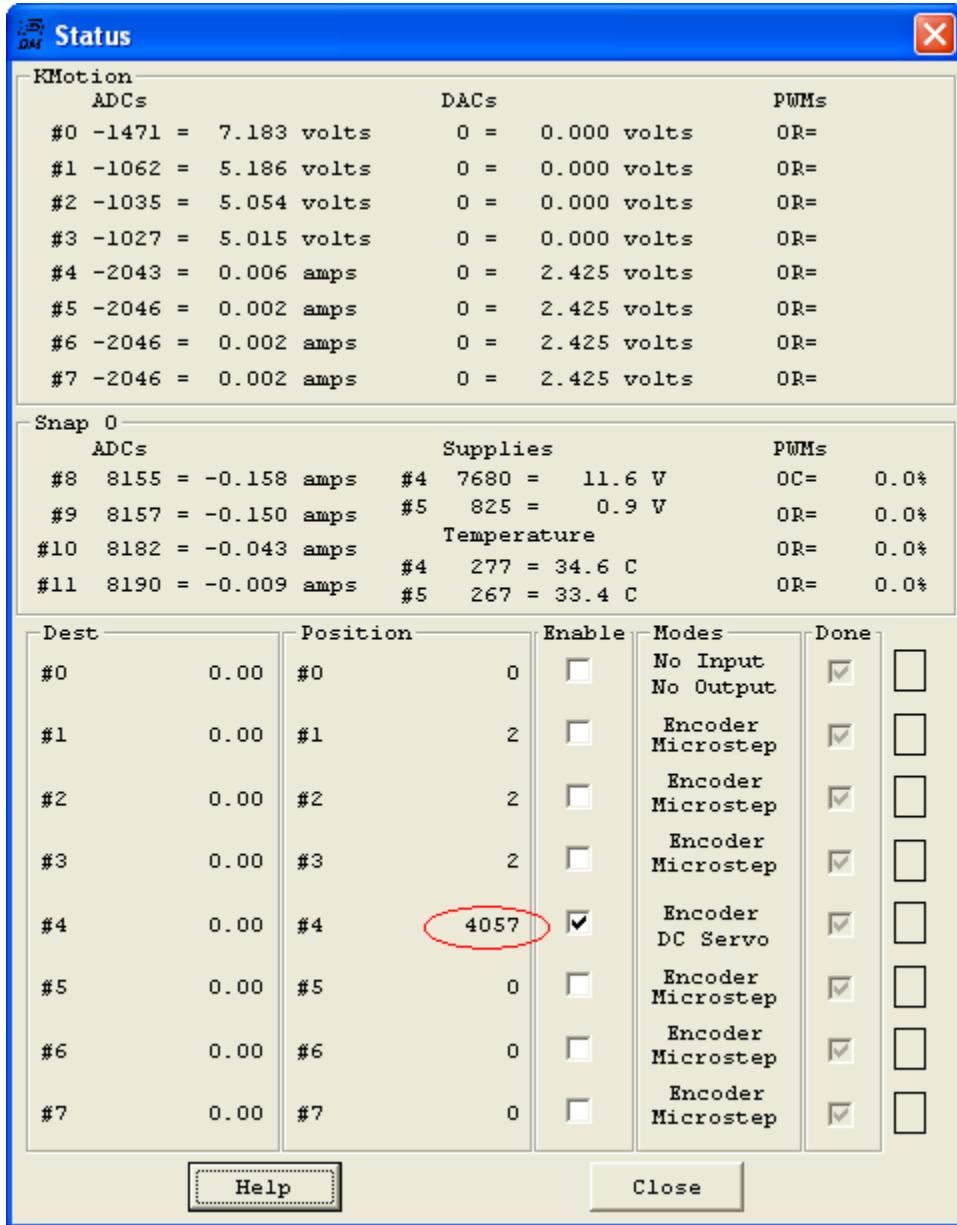

The Step Screen servo loop (PID) parameters are set to only very low proportional gain. The max output is set to a small value that should still allow some motor motion. SnapAmp DC Servo mode outputs current commands in the range of -1000 to +1000 which corresponds to approximately -30Amps to +30 Amps. So a max output of 100 will limit the current to 3 Amps. Although the Integrator will not be initially used we set the max integrator to also be 100. The max error is set to a large number. The motion profile parameters are set to values that we will expect to eventually achieve. Our example uses a low speed torque motor being driven off of only 12V. This encoder has 4000 counts/rev so a speed of 50,000 cnts/sec corresponds to 12.5 rev/sec (750 RPM).

With the Motor Power Supply tuned off, pushing the Enable button will download the parameters from all screens and enable the axis without any motor motion. This will allow us to ensure the axis is properly wired and configured as encoder input and of the correct encoder channel.

## Testing the encoder

We can now rotate the motor/encoder shaft by hand and should observe counts on Axis Channel 4 on the Analog Status Screen. Note if one of the other axis's configurations also is defined as input Encoder channel 0 then that axis may count as well. The default configuration for axis 0 is Encoder input from channel 0. To avoid confusion, disable any other axis by selecting that axis, define the input/output types as "No Input" and "No Output", then download, then disable the axis. To test the encoder, rotate the encoder and check if the expected number of counts per rev are obtained. Rotating the axis the opposite direction should count in the opposite direction.

## Testing the Motor Amplifier

In order to test the Motor Amplifier functionality Console commands (PWMC - Pulse-Width-Modulation Current Mode) will be entered to drive the motor in the forward and reverse direction. The axis should and must be disabled to issue these commands, otherwise they will be immediately overwritten with servo output commands. Small values should be used initially. Note: PWMC commands may only be used with a SnapAmp (Software Version 2.31 or later), the KMotion onboard amplifiers do not have current feedback mode so PWM commands should be used instead. SnapAmp's PWMC current commands range from -1000 to +1000 which corresponds to approximately -30Amps to +30 Amps. So a value such as 100 might be used to provide a drive of 3 Amps.

Before issuing the PWMC commands, SnapAmp's peak current fault levels should be set. After verifying that the axis is disabled (on the Analog Status Screen), load and execute the following program to set the peak current limits. The Fault Green LED on the SnapAmp should turn off. The "I'm alive" Green LED should remain blinking.

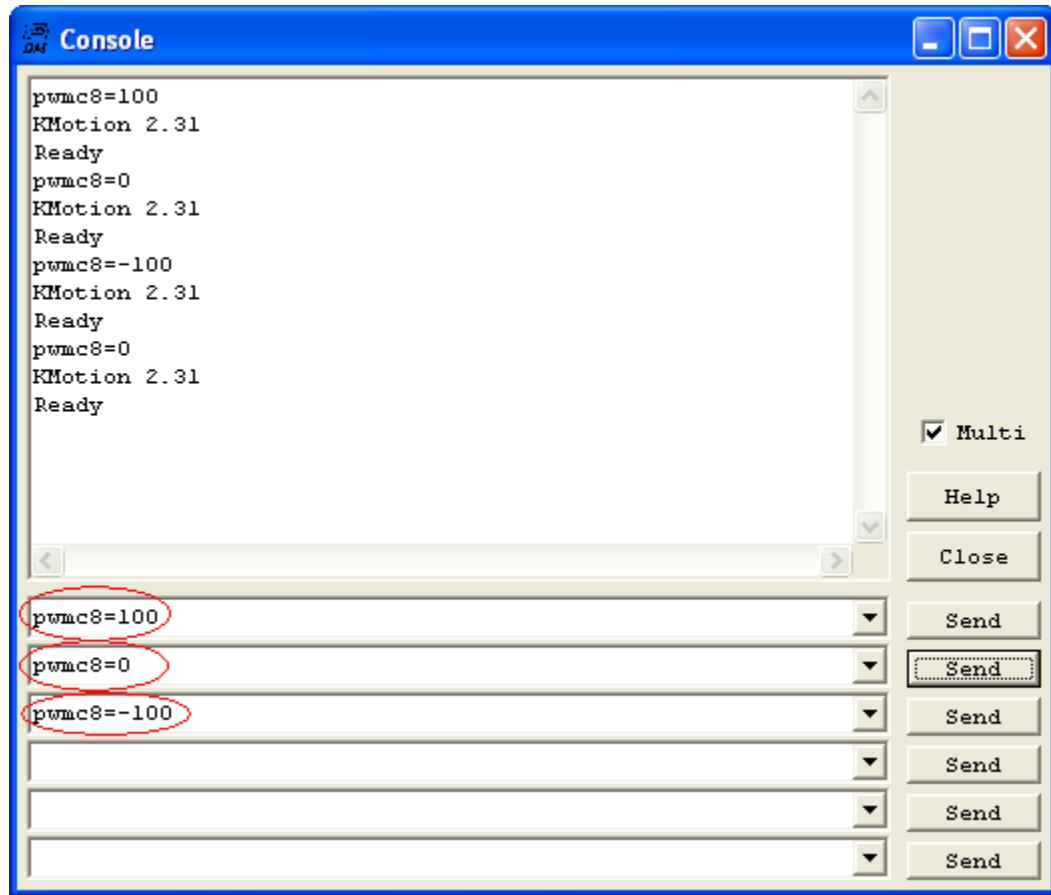

```
#include "KMotionDef.h"

main()
{
    // peak current limits

    WriteSnapAmp(SNAP0+SNAP_PEAK_CUR_LIMIT0,9);
    WriteSnapAmp(SNAP0+SNAP_PEAK_CUR_LIMIT1,9);
}
```

No Errors, No Warnings, text=156, bss=0, data=0, total=160

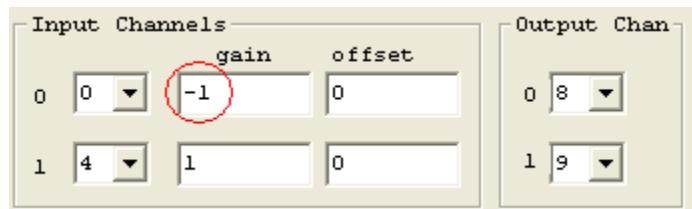

Setup the Console Screen as shown below. Sending the commands should drive the motor in one direction, then no motor drive, then drive in the other direction respectively.

## Closing the loop

If the motor and encoder are working we are ready to attempt to close the servo feedback loop. All that is required is to enable the axis by pressing "Enable" on the Step response Screen. Normally one of two things will occur. Either the axis will respond as a weak servo, or the servo will have positive instead of negative feedback and runaway from the target destination rather than toward the target destination.

If the servo has positive instead of negative feedback, something should be reversed. Either the Motor leads may be reversed, the encoder signals may be reversed, or a Input Gain of -1 may be entered on the Configuration Screen (as shown below).

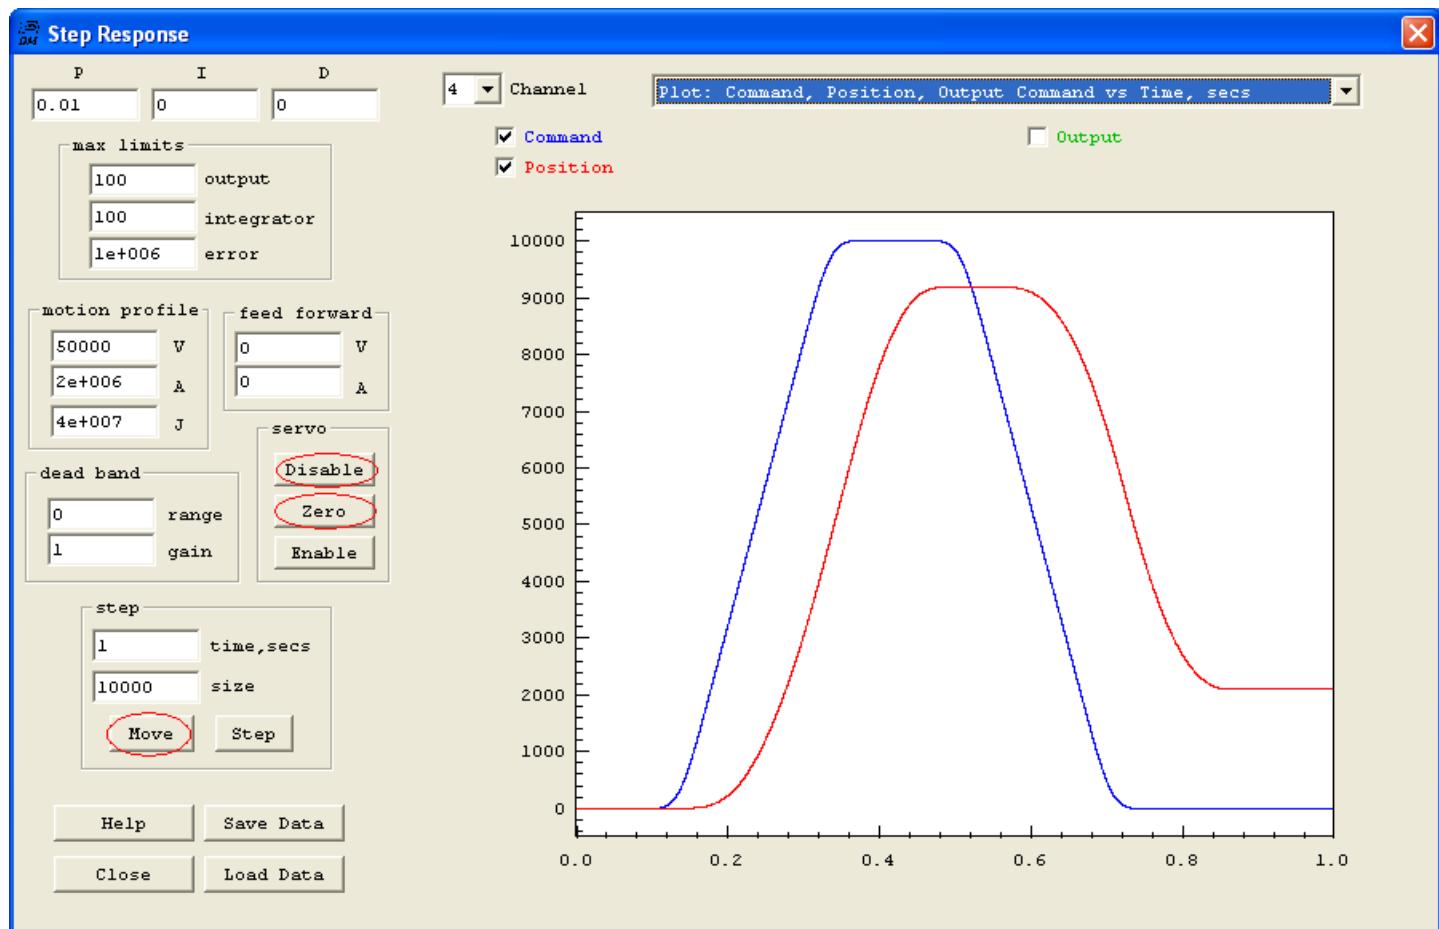

If the servo has proper feedback and responds as a weak servo, as the motor/encoder shaft is turned the servo will cause torque to restore the position back to where it was. With the example proportional gain of 0.01, turning the shaft 1 turn should generate an error of 4000 counts. 4000 counts multiplied by a gain of 0.01 = 40 PWM counts or  $40 / 1000 * 30\text{Amps} = 1.2 \text{Amps}$ .

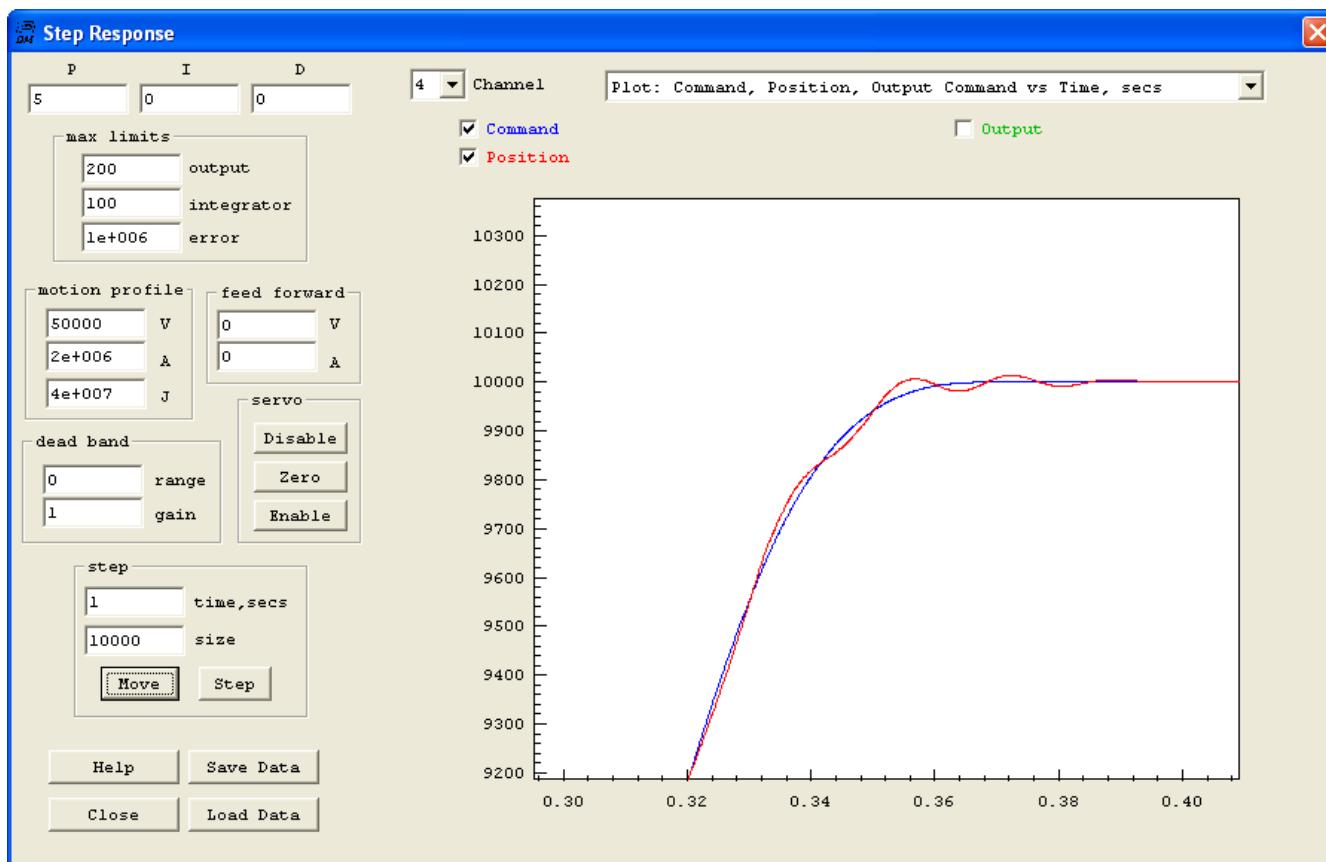

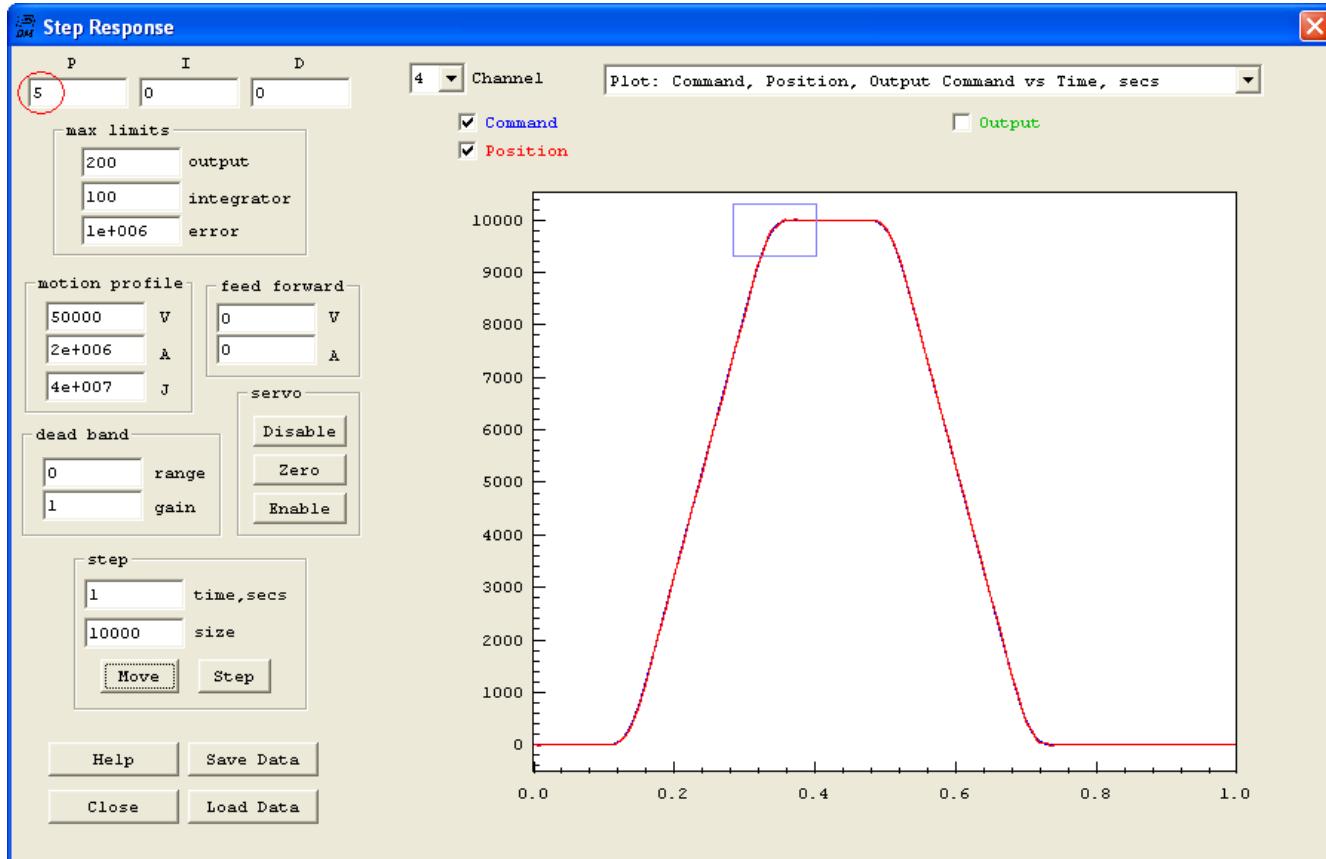

## Tuning the Servo

Once the servo loop is functional Servo Tuning should be performed to move the performance, hopefully up to the desired levels. Servo tuning is a complex subject that has been written about extensively. The basic idea is to increase the feedback gains in order to reduce following errors and speed of response without going unstable (oscillating wildly). KMotion has extensive plotting tools to help tune and understand how well a set of parameters performs.

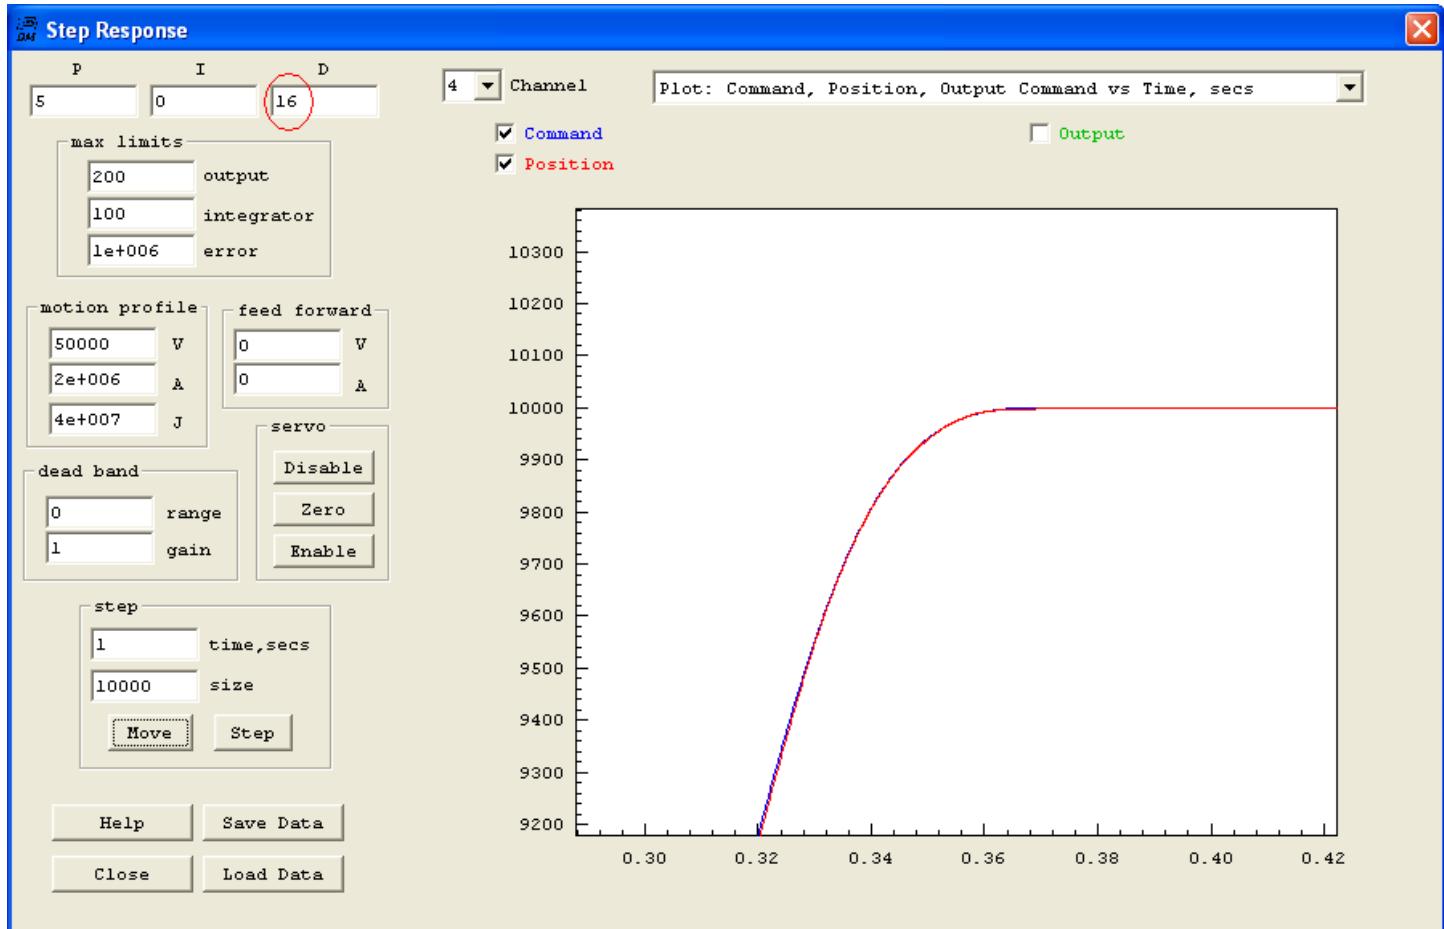

To test the current performance, disable the axis, manually move it to a position where it may move +10000 counts, then push the "Move" button. A plot such as that shown below should be observed. Set the plot type and axis selections to agree with those shown below. The blue plot is the desired path as defined by the motion profile and the motion is made for 10,000 counts and then a second motion is made back to zero. The red plot is the measured encoder position. Note that the red plot attempts to follow the blue plot but with a large error of thousands of counts. Gradually increase the P gain (possibly by factors of 2) while pushing the Move button and the following error should reduce. At some point the system will probably go into oscillation and become unstable. It may be necessary to disable the axis, reduce the gain, and re-enable the axis.

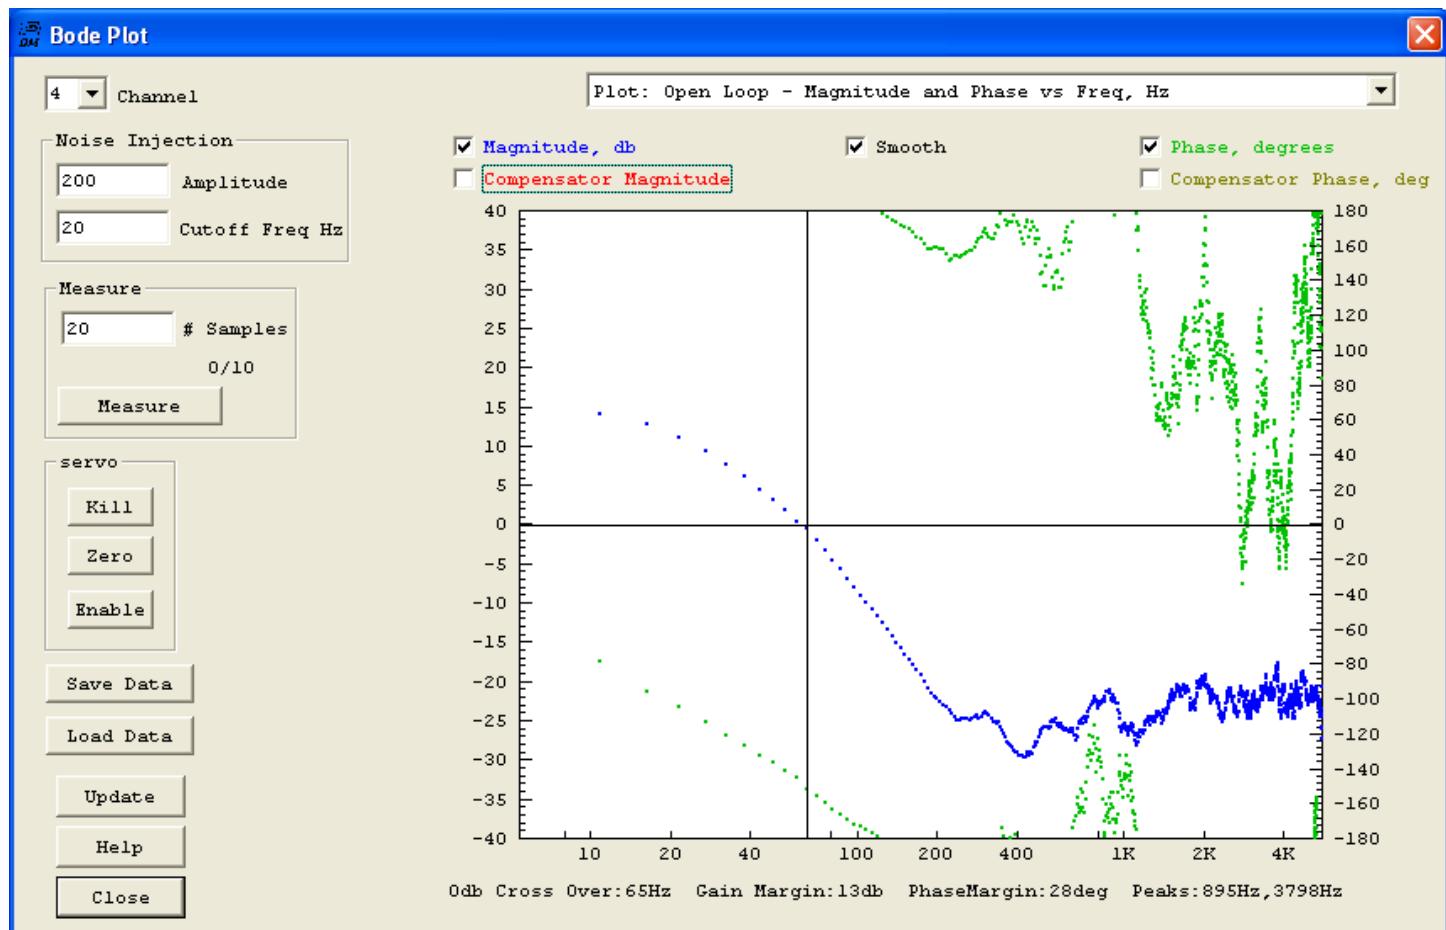

Increasing the gain 500X (from 0.01 to 5) results in a much better response. Notice the blue (desired) plot is almost completely hidden behind the red measured plot. However by zooming in to the purple rectangle (left click mouse drag) we can see oscillation. See the second plot below.

Increasing the derivative gain can often reduce oscillation. In the plot below we have set the D gain to 16. Notice the oscillation has been reduced.

A Bode plot is useful in understanding the frequency response and for designing advanced servo loop filters. Below is the Bode plot response of the system. Important features to look for in a Bode plot is where the Magnitude (blue plot) first passes through the 0 db line. This is the bandwidth of the system. Another important measure is the "phase margin" which is how far away the phase is from -180 degrees when the magnitude is at 0db. In this case the phase margin is 28 degrees. See the Bode Screen in the main Help section for more information

## Executing a simple C Program Motion Sequence

The C program below is an example of a simple program to perform a sequence of moves and repeat. There are 5 moves of 8000 counts (2 motor revs) and then a move back to the start. After each small move there is a wait until the motion is complete followed by a 0.2 second delay. [Here](#) is a video of the mechanism executing the motion.

```
#include "KMotionDef.h"

main()
{
    for(;;)
    {
        Move(4,8000);
        while (!CheckDone(4));
        Delay_sec(0.2);

        Move(4,16000);
        while (!CheckDone(4));
        Delay_sec(0.2);

        Move(4,24000);
        while (!CheckDone(4));
        Delay_sec(0.2);

        Move(4,32000);
        while (!CheckDone(4));
        Delay_sec(0.2);

        Move(4,40000);
        while (!CheckDone(4));
        Delay_sec(0.2);

        Move(4,00000);
        while (!CheckDone(4));
    }
}
```

## Configuring Closed Loop Step and Direction Outputs

The Closed Loop Stepper Mode works much the same as open loop Step and Direction Output Mode except there is also an error feedback correction term. In fact, if the gains of the correction term (PIPs) are set to zero then the mode will behave the same as an open loop Step Direction Mode. This mode is much easier to “tune” than a stepper driven as a brushless motor and unlike a brushless motor there are no commutation issues. A good application for this mode is a stepper with linear glass scales. The main feature is the position feed forward with fixed gain of 1.0. See the flow diagram below. Without any correction it behaves just like a stepper. As correction gains are added, corrections for drift, friction, load forces, or even a miss step are made. One disadvantage is that the motor can still stall. After the stall and after the motion stops the servo loop could then gradually correct the position which could be of value in some applications.

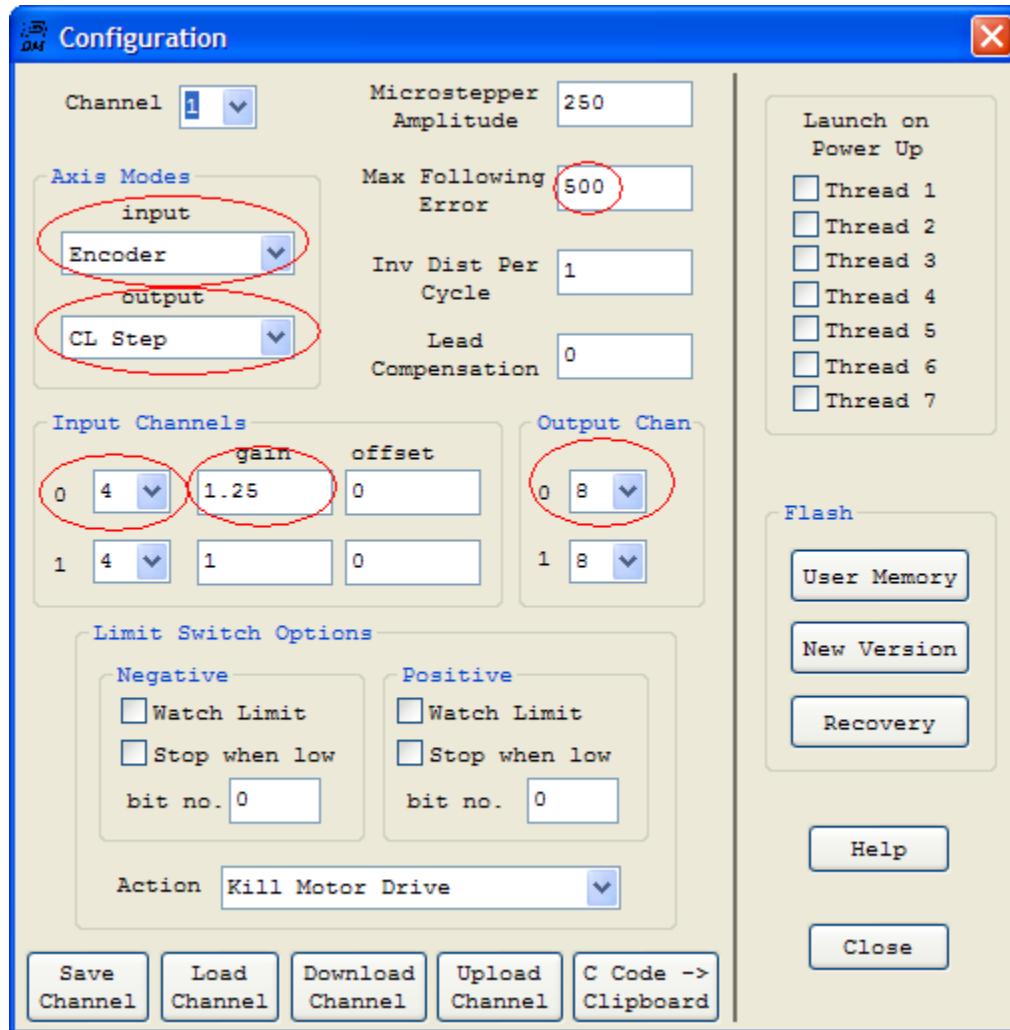

## Closed Loop Stepper Flow Diagram

To Configure an axis as a Closed Loop Servo select "CL Step" as the output mode for the axis as shown below. Any input mode may be used as position feedback, but the most common is a quadrature encoder either on the motor shaft or as a linear glass scale.

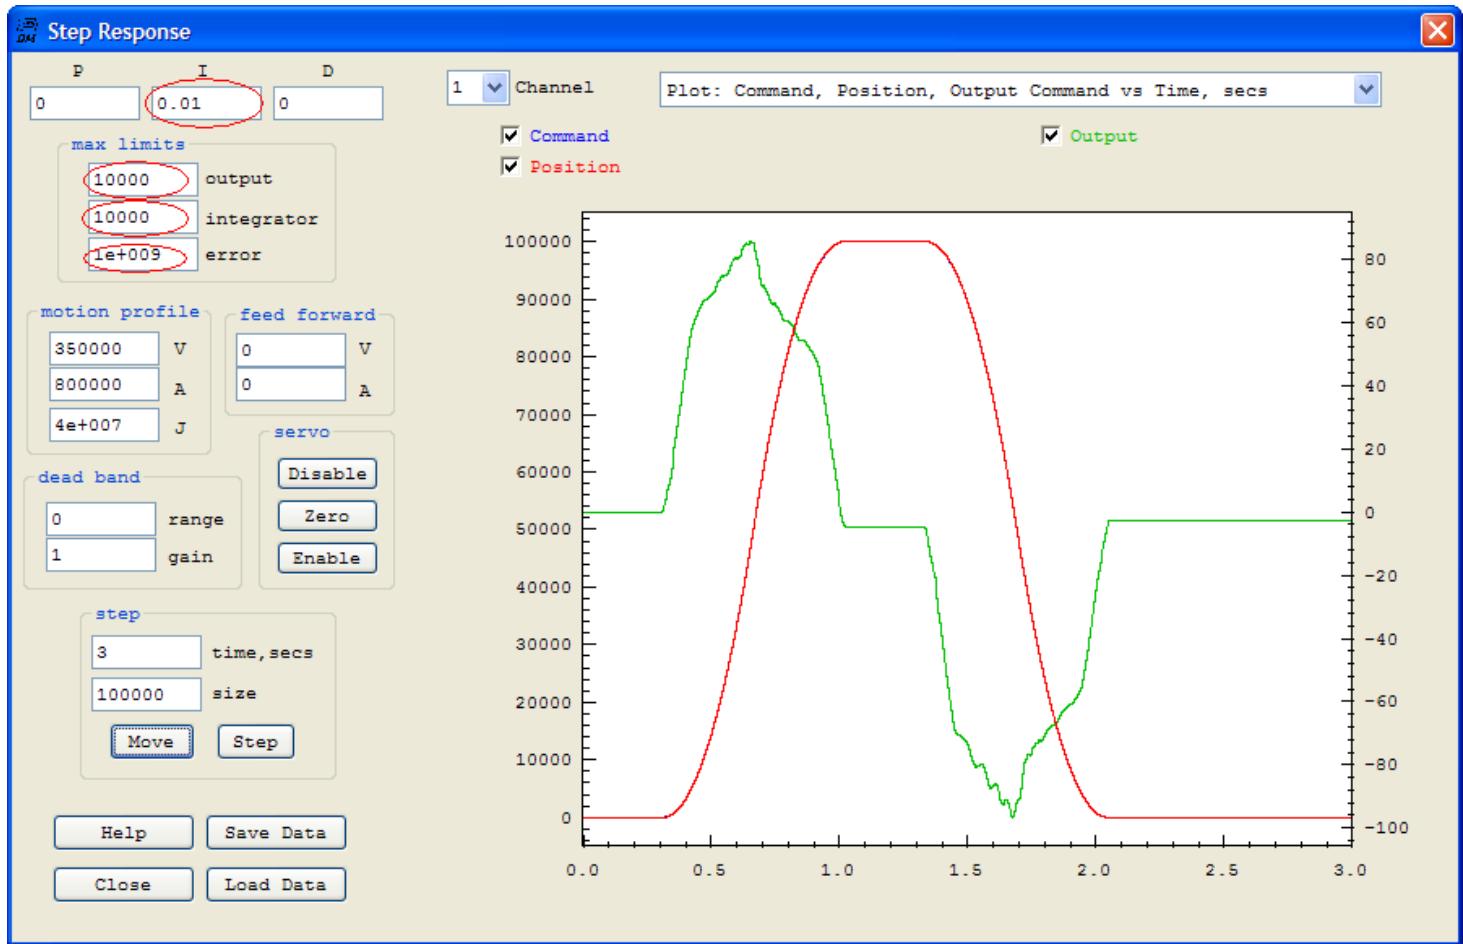

Note that an Input gain of 1.25 is used in this example. This was calculated from the ratio of the number of  $\mu$ Steps/rev to the number of encoder counts/rev. (A micro stepper amplifier set to 50 microsteps/full step and a standard stepper motor with 200 full steps/rev will have 10,000  $\mu$ Steps/rev, a rotary encoder with 2000 lines/rev will produce 8000 quadrature counts/rev,  $10000/8000 = 1.25$ ). The raw axis units will be in  $\mu$ Steps.

Max Following Error may be used to trip an axis disable when exceeded.

Important PID parameters are shown below circled in red. The I (Integrator) gain of 0.01 is probably the most important. Your system may require more or less. Too much and the system may over shoot or become unstable (oscillate). Too little and corrections will be made slowly. Because we are measure the position and also commanding a position Integrator control works well. An integrator will ramp the output at a rate proportional to the amount of the error. This "slowing as we get closer" will result in an exponential curve approaching the target. Backlash, friction, delays, and other factors will eventually cause the system to overshoot and become unstable with too much gain.

Max limits may also be useful for limiting the correction. In this example the limits are set to large values. Limiting the max error to a small value will limit the maximum slew rate of the Integrator. Max Output and Max Integrator are similar for an Integrator only compensator and will limit the maximum amount of correction that can be made.

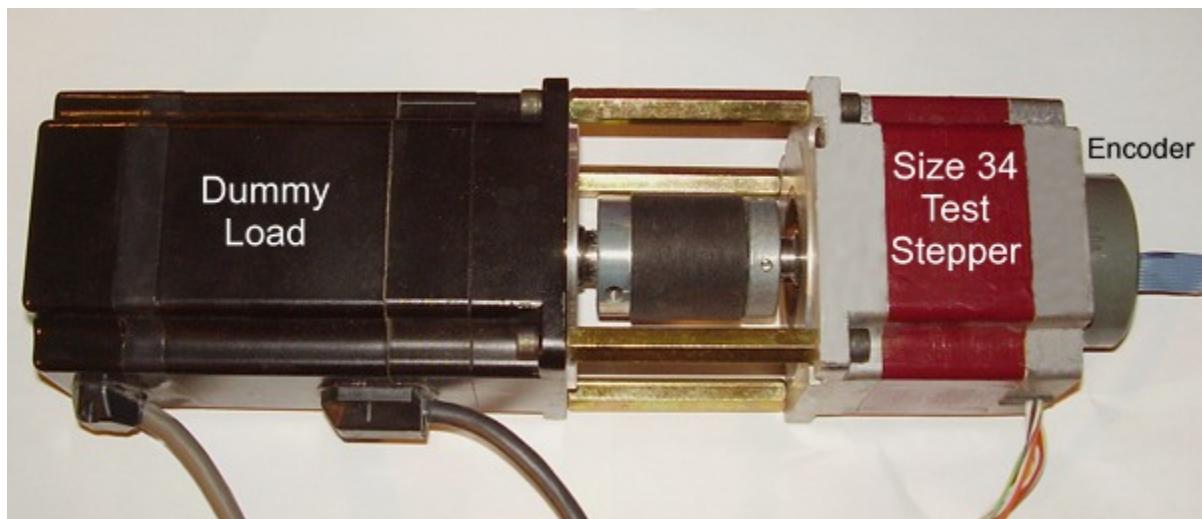

A 2nd order Low Pass Filter is also used in this example to make the system more stable by reducing high frequency corrections. Note a cutoff frequency of 100Hz with Q 1.4 is used. After specifying the filter the Compute Button must be pressed to compute the Z domain IIR Coefficients that are downloaded and used by KFlop.

**Filters**

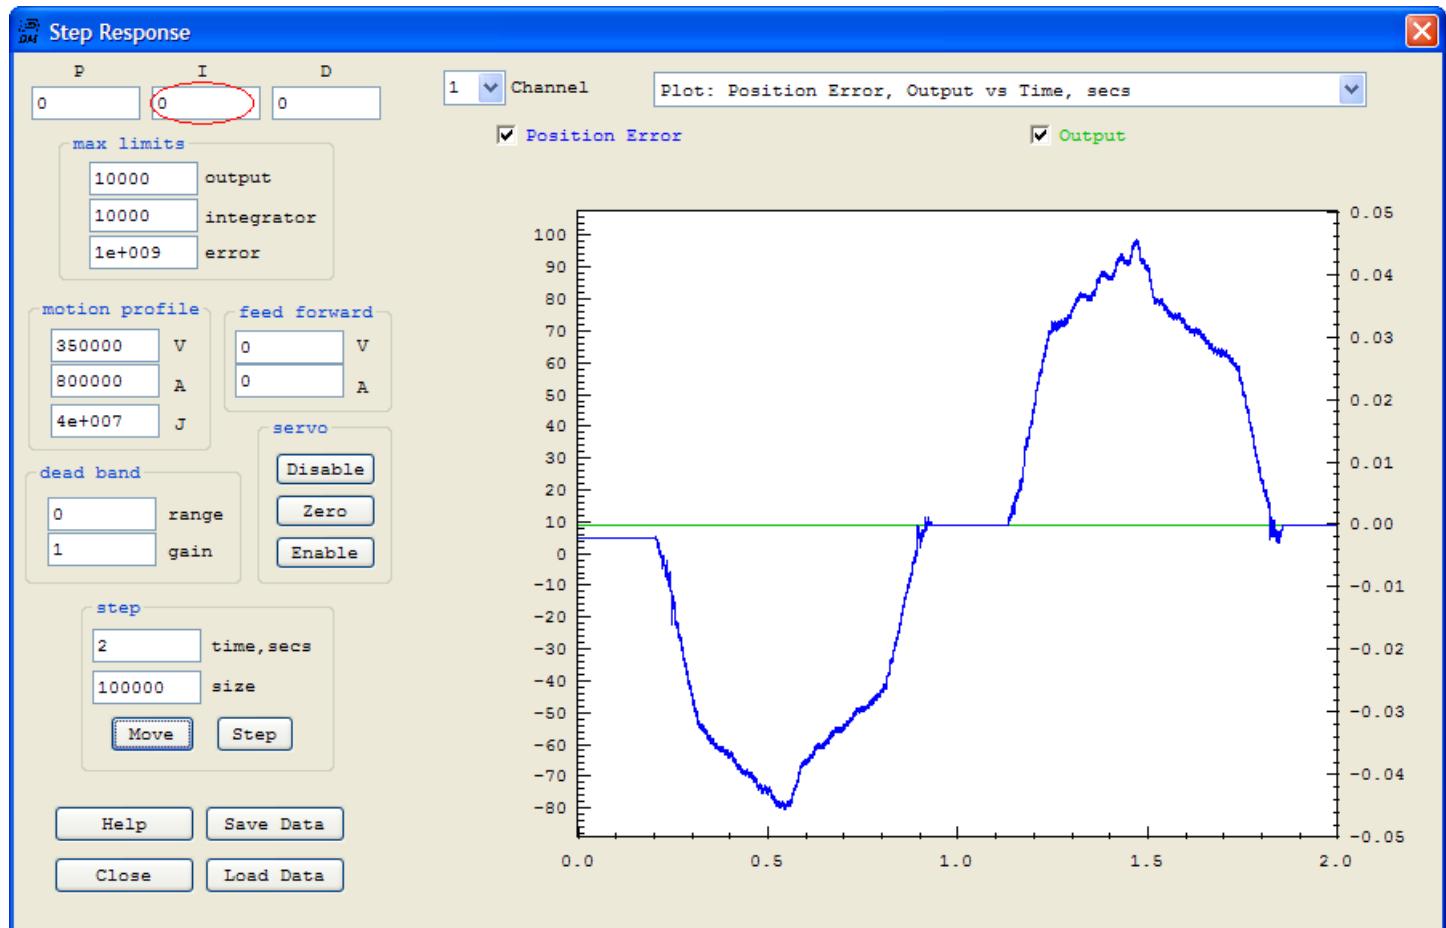

Filter 0	Filter 1	Filter 2

Test Mechanism with Size 34 Stepper with encoder connected to a Dummy Load.

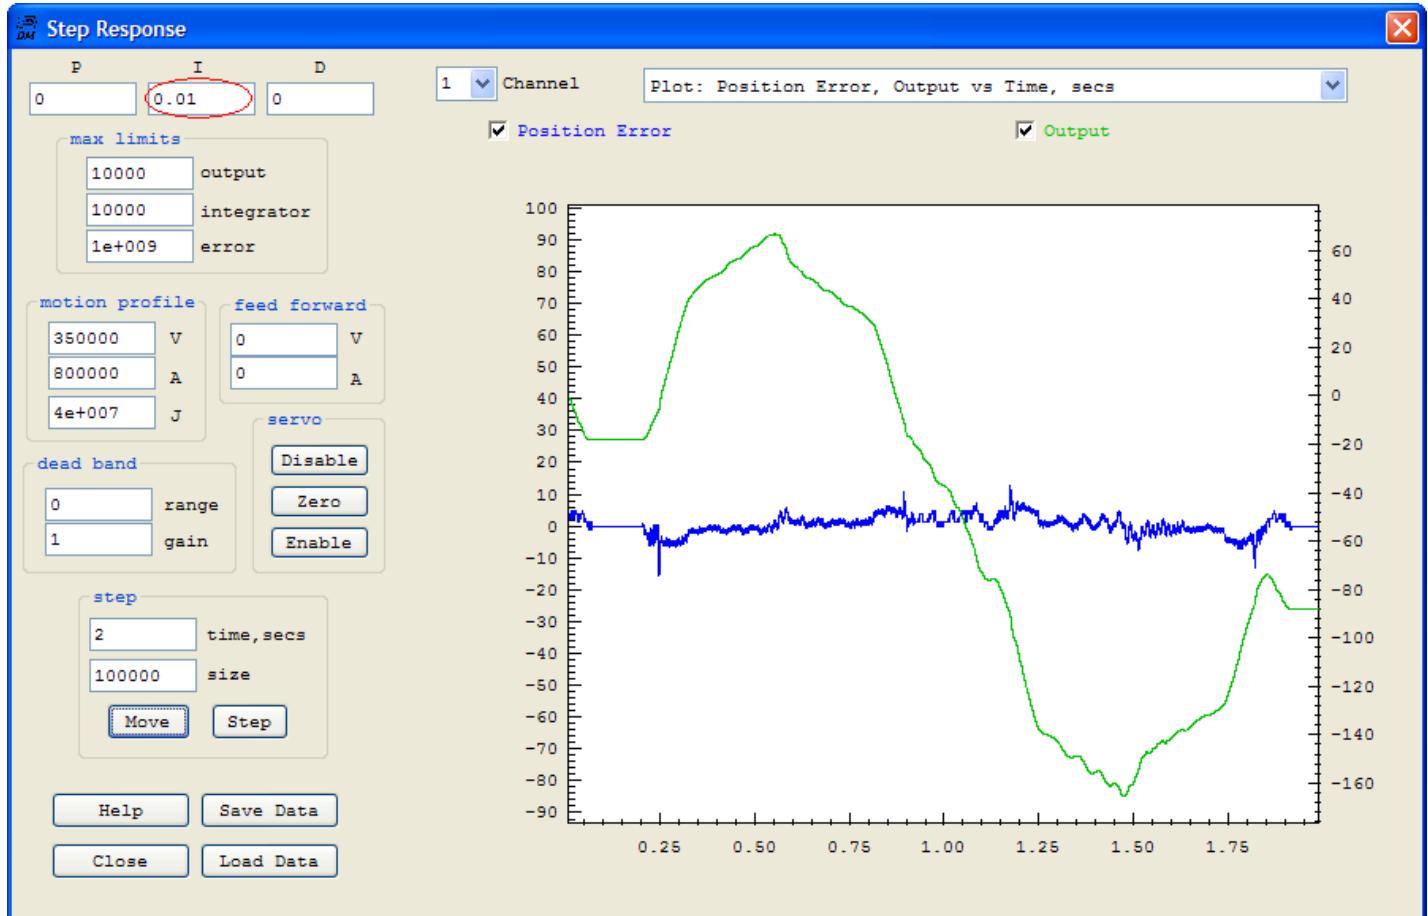

Test Move of a Size34 Stepper with 50 usteps/full step forward and backward at 4000sps

With PID gain zero (no correction). Note encoder shows errors of ~100uSteps

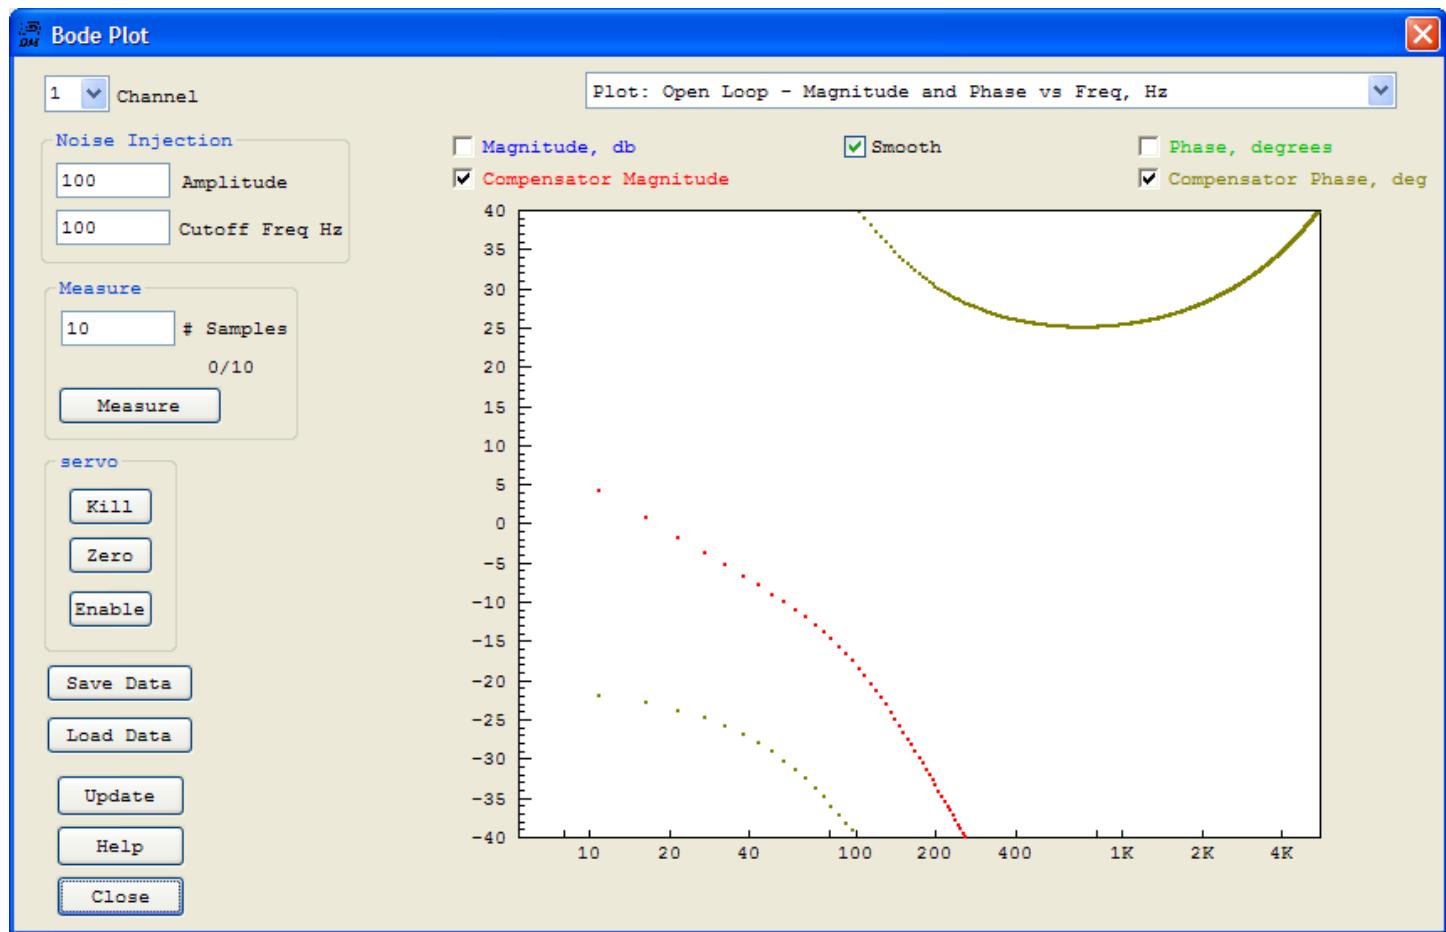

Integrator gain now set at 0.01. Also 2<sup>nd</sup> Order 100Hz Low Pass Filter Q=1.4 used

Note error is reduced. Blue plot is position error, green is the Output (correction offset)

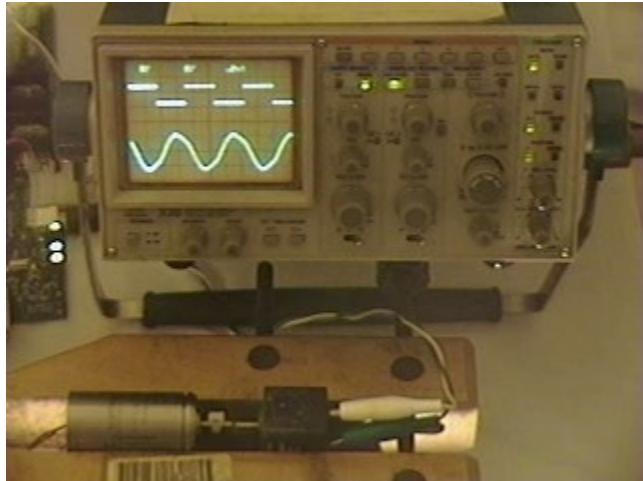

A Bode Plot of the Compensator PID + LP Filter response. I=0.010 and 2nd order Low Pass 100Hz @ Q=1.4. Red plot is Magnitude.

Note that errors less than about 20 Hz will be corrected. Correction gain drops below 1 (0db) at higher frequencies.

## Configuring a Resolver as Input to KMotion

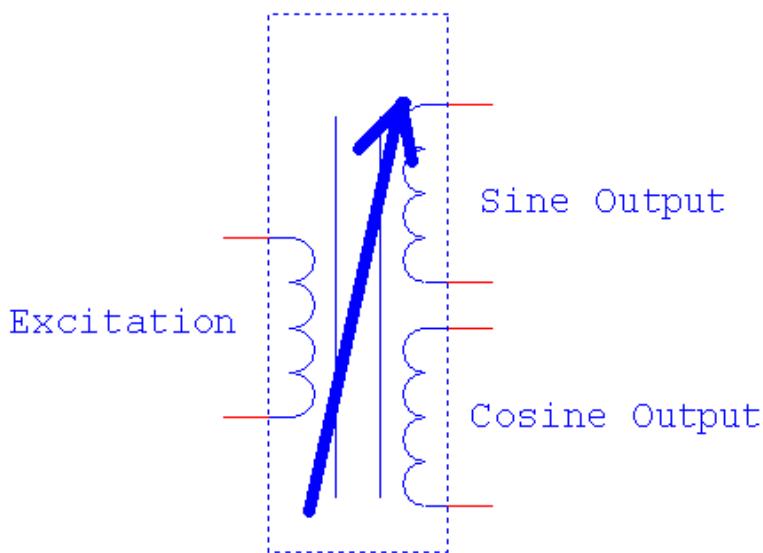

[Here is a video overview.](#)

This example configuration shows a Resolver used as a KMotion input device. A Resolver serves a purpose much like a digital encoder. A Resolver is physically somewhat similar to a transformer with two output windings called sine and cosine outputs. For a given excitation input, the amplitude of the sine output is proportional to the sine of the mechanical rotor position, and the amplitude of the cosine output is proportional the cosine of the mechanical rotor position. By driving the excitation coil of a Resolver and measuring the amplitude of the sine and cosine outputs, the mechanical rotor position can be determined. Although a Resolver is an analog device there are some significant advantages. A resolver is a high reliability device originally developed for military applications. Because a Resolver is able to determine the rotor position in an absolute manner for an entire shaft revolution it is not possible to "lose" position of a fraction of a shaft revolution, as with an encoder. If the position is "lost" it must be lost by a complete multiple of an entire shaft rotation. Often older CNC systems used Resolvers as their feedback device. When using KMotion to retrofit an older system with resolvers, because KMotion may be used with resolvers, it is not necessary to modify the original system to change to digital encoders.

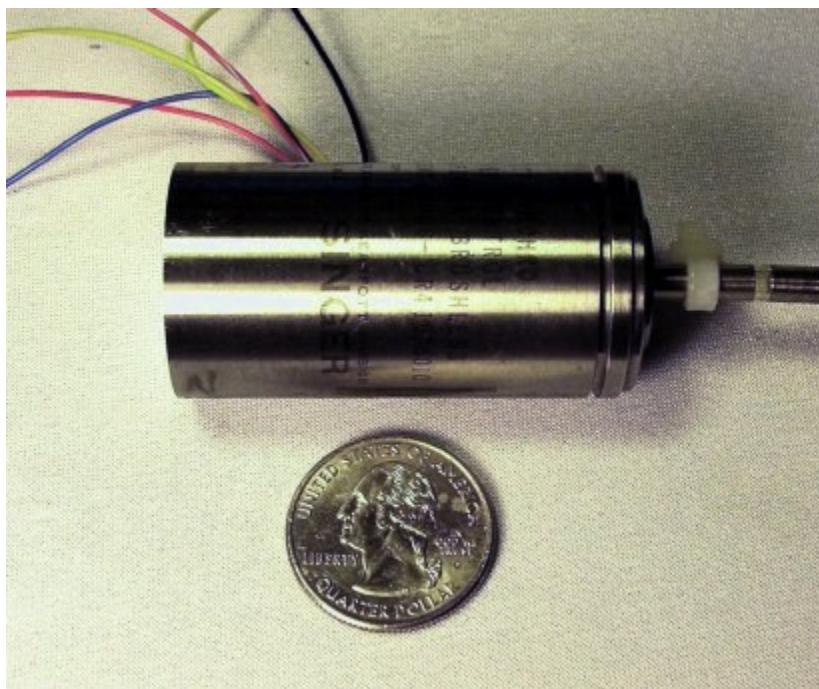

Note: many older systems used a resolver in a somewhat reverse manner. The controller excited the sine and cosine coils in a manner such that third coil would generate a signal proportional to the *difference* between the desired rotor position and the actual rotor position. This difference was then used to directly drive the servo motors to reduce the error. Operating in this manner the controller has no information on the actual rotor position or the following error between the desired and actual rotor positions. A resolver originally used in this manner may still be used in the manner described in this example.

Shown below is a schematic symbol of a Resolver. The arrow indicates a varying coupling between the excitation input and the output coils as a function of rotor angle.

## Resolver

Here is a typical resolver unit (manufactured by Singer) with 6 wires, two for each of the three coils. The wiring of a resolver can usually be determined using a simple ohmmeter. The ohm meter can be used to determine which pair of wires belong to a coil. Furthermore the sine and cosine coils should have a very similar resistance and usually different from the excitation coil. In the resolver shown below the excitation coil has a resistance of 20 ohms and the sine/cosine coils have a resistance of 37 ohms. Swapping the sine and cosine coils will simply reverse the measured motion.

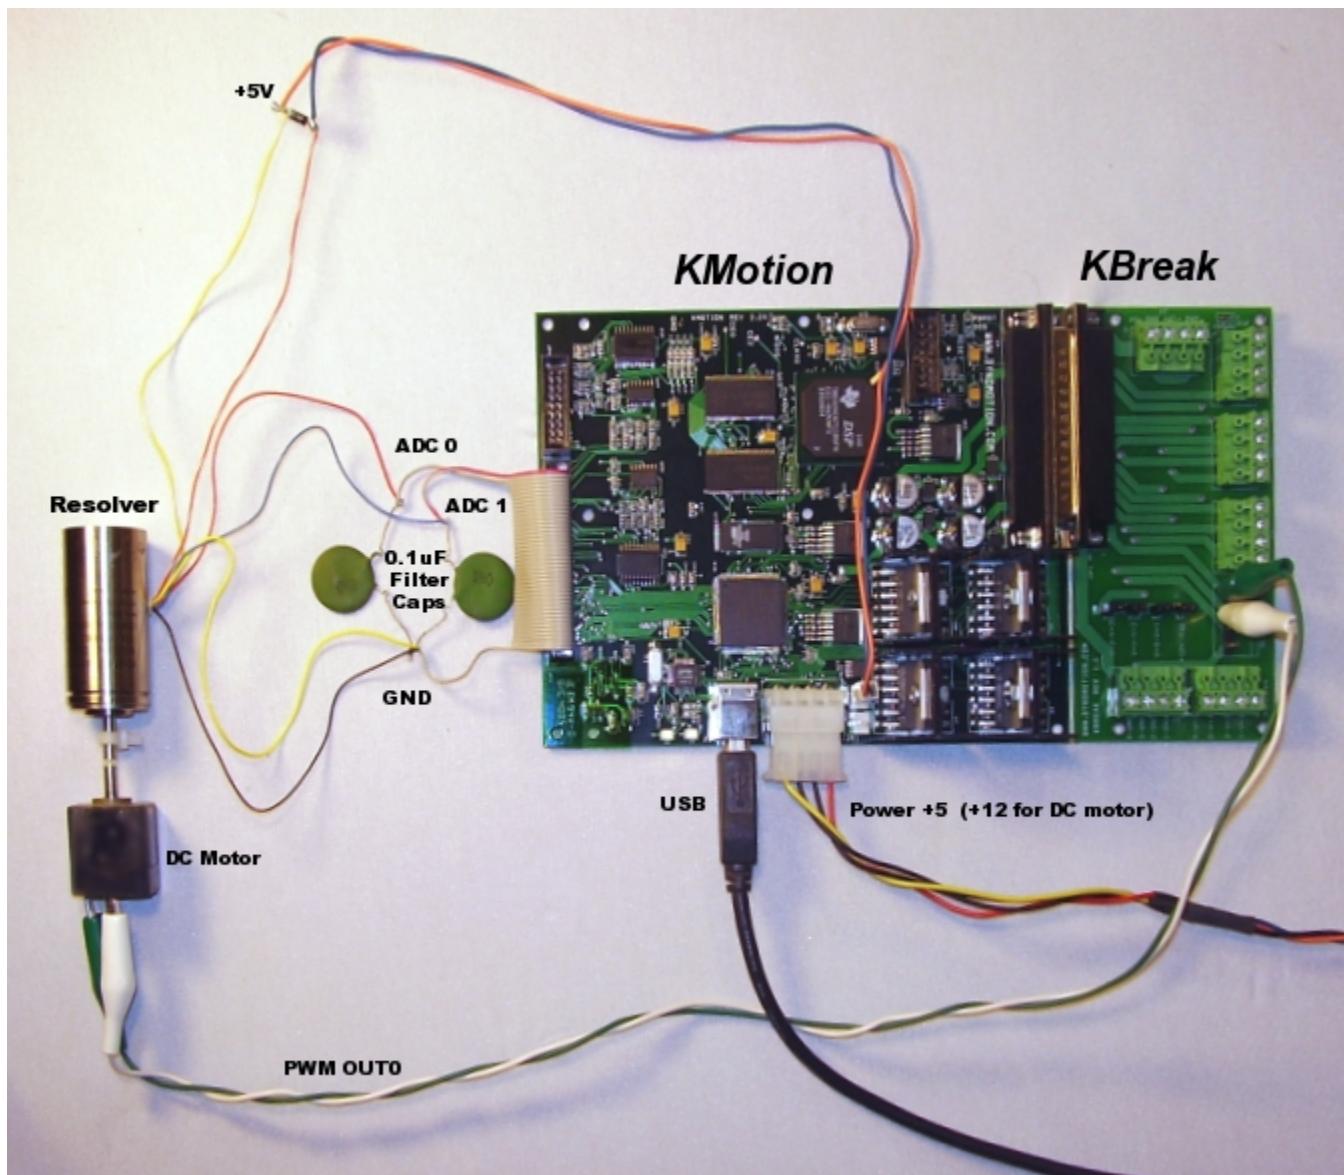

Resolvers may be interfaced to KMotion in one of two ways. One method is where an external circuit or module is available to excite the resolver and determine the sine and cosine magnitudes externally. In this case only the sine and cosine magnitude signals need to be connected to ADC inputs and "Resolver" input mode can be selected. For further information regarding this interface method see the Configuration Screen Setup.

A second method is where KMotion performs the excitation and synchronously samples the AC outputs to determine and track the Resolver position. The second method doesn't require an external Resolver Control Module or control circuit. Only a single diode and two filter capacitors are required. This is the method used in this example configuration. The method does require a KMotion User Program (shown below written in C) to switch the resolver excitation on and off and to sample the output waveforms at the appropriate times to determine the amplitudes.

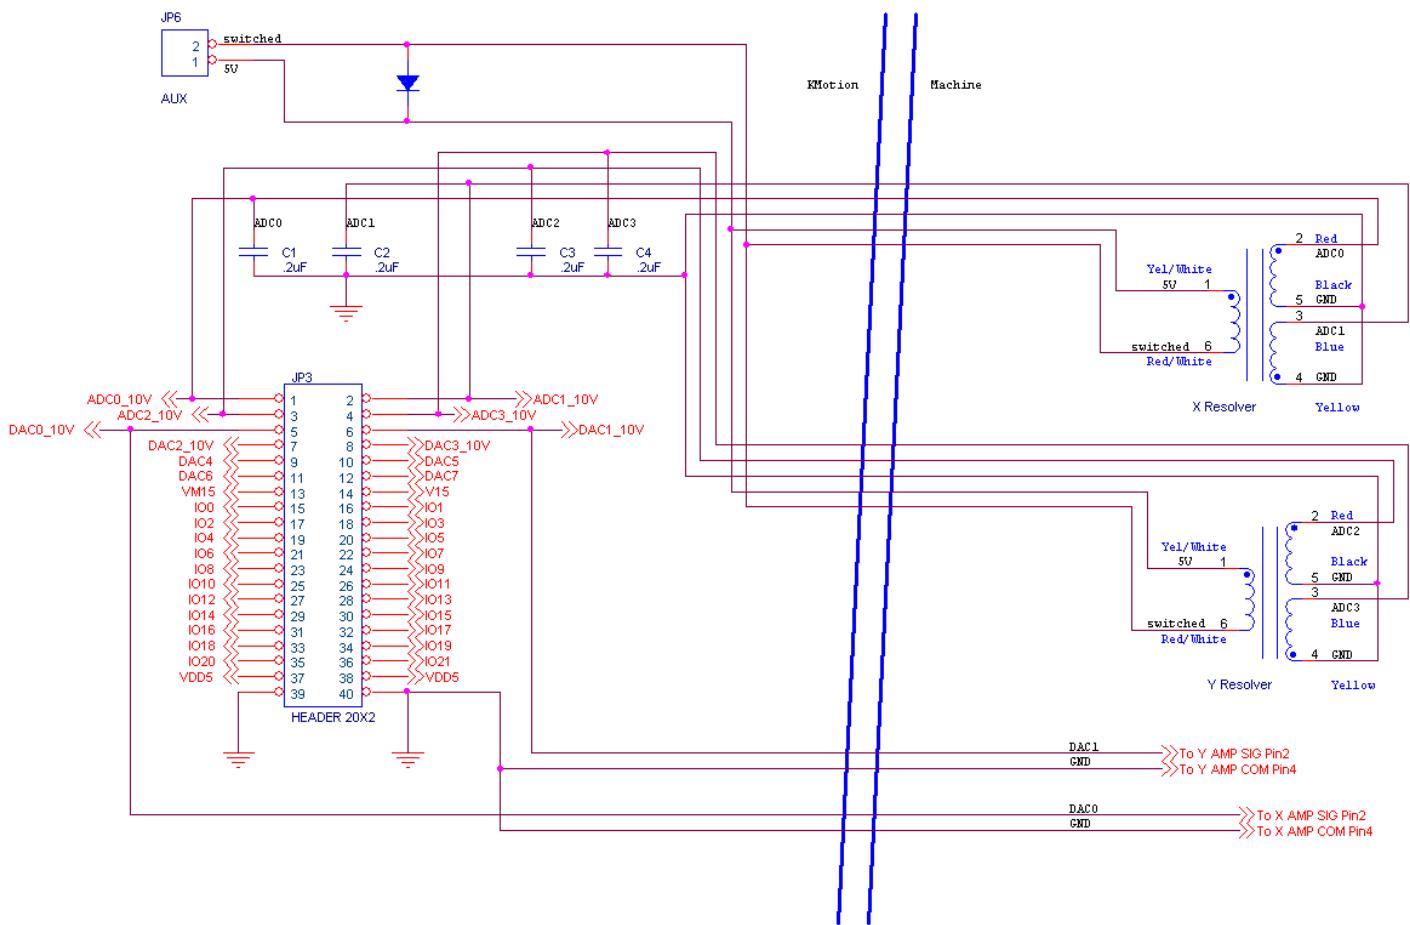

KMotion's Aux Switch output is used in this example to excite the resolver's input coil with a 5V square wave. +5V is applied to one end of the coil and the Aux Switch drives the opposite end of the coil to ground. This applies +5V to the coil which causes current to ramp up in the coil. When the switch is turned off, current is allowed to recirculate through a diode which will cause the current to ramp down due to the coil's internal resistance. This process is repeated every 4 User Program Time Slices (180us each) or every 720us (1.4KHz). The User Program computes the resolver position on both the positive and negative transitions so the effective update rate is 2.8 KHz. This Aux Switch output, and single diode, may be used to drive several resolvers.

The two output coils of each resolver are each connected to an ADC input with the other ends of the coils connected to ground. 0.2uF filter capacitors are used to smooth the output waveforms and should be located near the KMotion Board.

The example layout below shows the connections for a single resolver. Because KMotion has only 4 ADC inputs, KMotion is limited to interfacing to two resolvers. If more axes are required then digital encoders must be used. For testing purposes a small DC torque motor is shown connected to the resolver. The DC motor is driven from one PWM output using the +12V supply. A more likely scenario for an actual CNC retrofit would be to use the existing motor power amplifiers driven by KMotion's +/-10V DAC outputs.

A wiring diagram for a complete 2 axis resolver is shown below. Also shown is the DAC output connections for connecting to external power amplifiers with +/-10 V Inputs.

This is a KMotion User Program which basically loops every 4 time slices (720us), switches the 5V excitation, samples the ADC readings, computes the output magnitudes, and calls an internal function (DoResolverInput2) that computes the rotor angle and updates the axis's Position. DoResolverInput2 internally multiplies the measured angle (in Radians) by 1000/(2 pi) so that 1 shaft revolution will be seen as 1000.0 counts. This causes numeric values to have similar ranges as with digital encoders.

```
#include "KMotionDef.h"

// Two Axis Resolver Program 1/6/08
//
// outputs square wave to both resolvers using Aux Switch Output
//
// then samples output coils near positive and negative peaks
// takes the difference to compute magnitudes
//
// these ratios are used to match the amplitudes of sine:cosine

#define RATIO0 (978.0f/768.0f) // size j/size k
#define RATIO1 (950.0f/709.0f) // size n/size m
```

```

main()
{
    int i=0;
    int k0,j0,k1,j1;
    int m0,n0,m1,n1;

    SetBit(28); // +/-15V on
    SetBitDirection(30,1); // configure AUX switch as output
    DefineCoordSystem(0,1,-1,-1); // Define 2 axis system

    Delay_sec(0.1); // wait for +/- 15V to be stable
    for (;;) // repeat forever
    {
        WaitNextTimeSlice(); // wait a few servo cycles
        WaitNextTimeSlice();
        Delay_sec(10e-6); // wait for ADC conversion to complete
        k0=ADC(0); // Sample all the ADCs
        j0=ADC(1);
        m0=ADC(2);
        n0=ADC(3);
        SetBit(30); // Switch the resolver excitation

        //compute & track position based on measured magnitudes
        DoResolverInput2(ch0,(k1-k0)*RATIO0,j1-j0);
        DoResolverInput2(ch1,(m1-m0)*RATIO1,n1-n0);

        WaitNextTimeSlice(); // wait a few servo cycles
        WaitNextTimeSlice();
        Delay_sec(10e-6); // wait for ADC conversion to complete
        k1=ADC(0); // Sample all the ADCs
        j1=ADC(1);
        m1=ADC(2);
        n1=ADC(3);
        ClearBit(30); // Switch the resolver excitation

        //compute & track position based on measured magnitudes
        DoResolverInput2(ch0,(k1-k0)*RATIO0,j1-j0);
        DoResolverInput2(ch1,(m1-m0)*RATIO1,n1-n0);

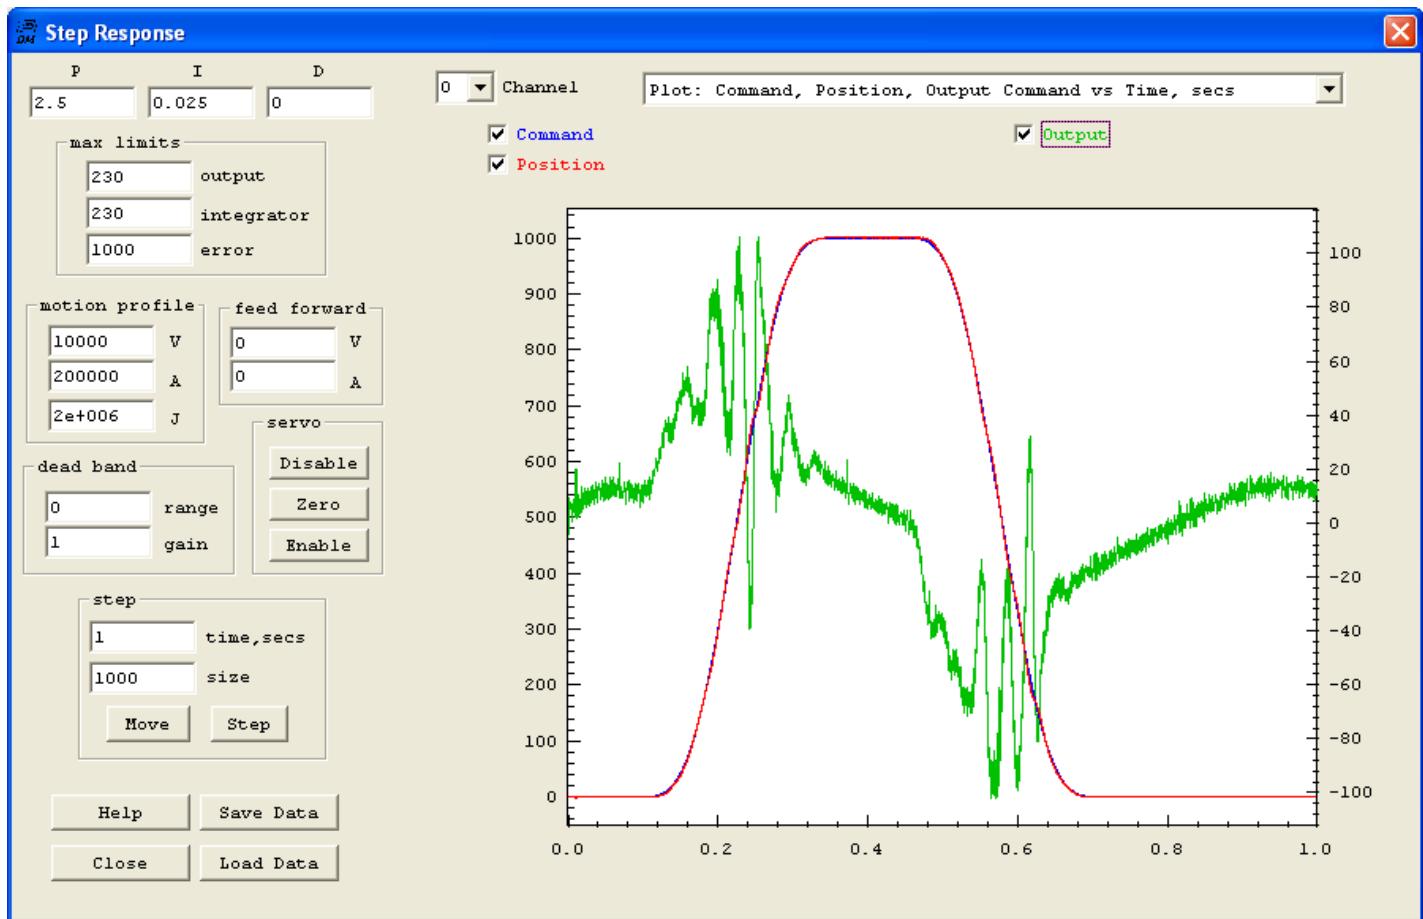

#if 0 // enable this to print the magnitudes occasionally
    if (++i==1000)
    {
        i=0;
        printf("%5.0f %5d\n",k1-k0,j1-j0);
    }
#endif
    }
}

```

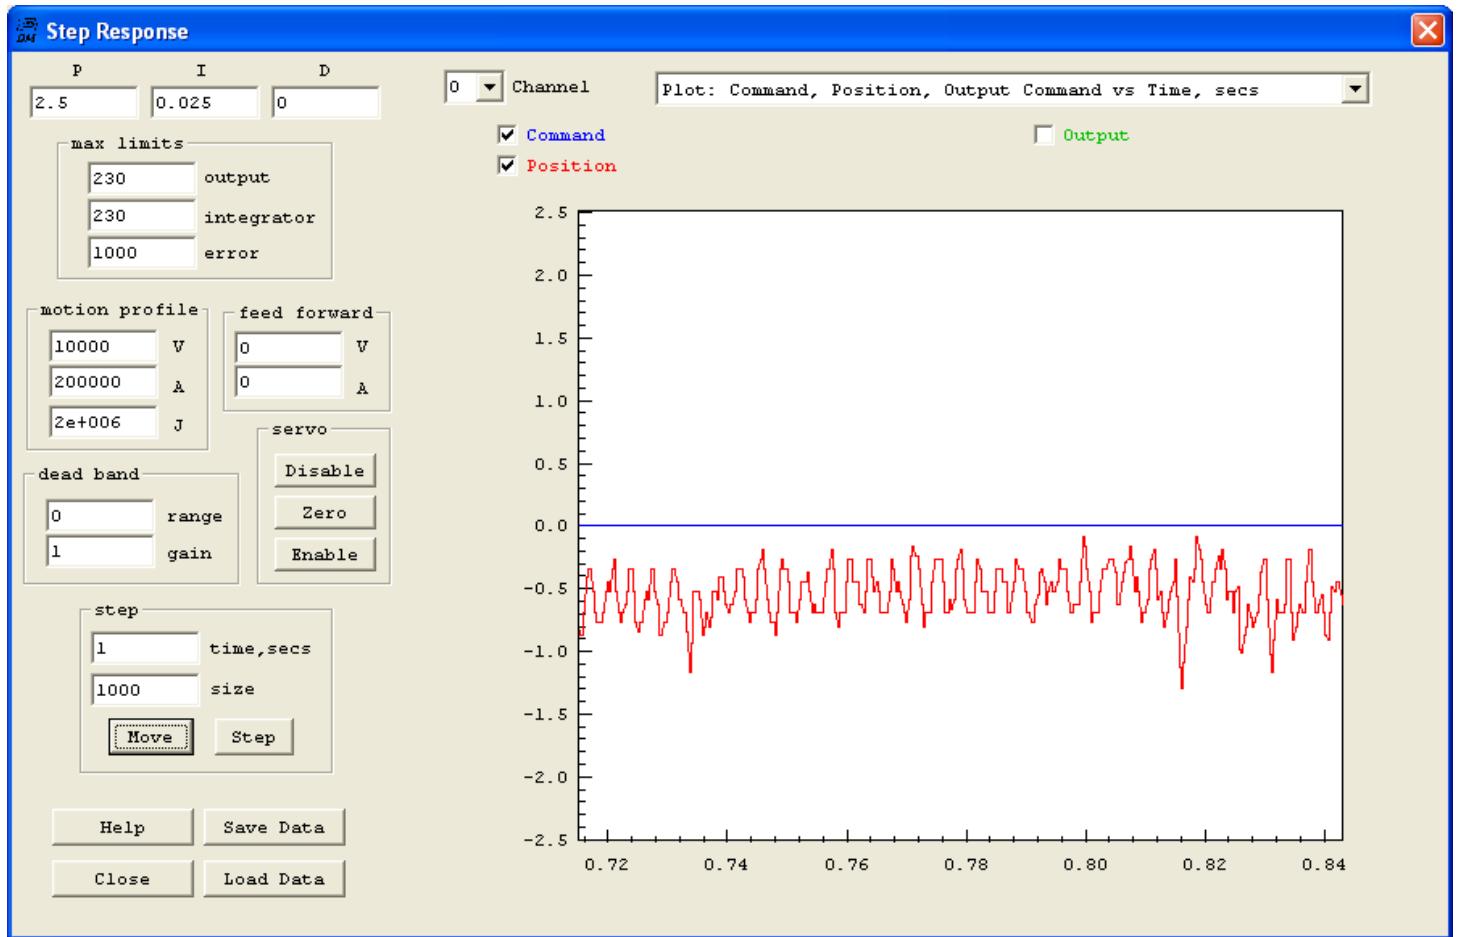

The Configuration Screen input mode is shown here set to "User Input". This allows the User Program shown above to be in charge of setting the current position.

Here is a Move Plot of a move of 1000 which corresponds to 1 shaft revolution of the encoder. Not the Command (Blue) and Measured (Red) positions are nearly overlaid.

Zooming in on the position gives an indication of the position resolution and noise level. The signal shown below has a range of approximately +/- 0.5 counts where 1 count is 1/1000 of a shaft resolution. So for example on a system with a 5 pitch lead screw (0.200 inches / rev) this would correspond to +/- 0.1 mils (~ 2.5um).

## Data Gathering

**KMotion** provides a flexible method for capturing data of all types every servo sample period (90µs). This same method is how **KMotion** gathers step response and Bode plot data.

Basically a list of addresses and data types are defined. An end address of where to stop capturing data is set, and when triggered the Servo Interrupt will capture the specified data values. All values are converted to double precision numbers before being placed into the gather buffer. The maximum size of the Gather Buffer is 1,000,000 double precision values (8 MBytes).

```
#define MAX_GATHER_DATA 1000000 // Size of gather buffer (number of doubles, 8 bytes each).
```

The following example shows how to setup to capture the two PWM drives (for a stepper motor) and the commanded destination for a 0.5 second time period, trigger the capture, make a simple move, wait until the capture is complete, and print the results.

```
#include "KMotionDef.h"

main()
{
    int i,n_Samples = 0.5 / TIMEBASE;

    gather.Inject = FALSE; // Don't inject any Data anywhere

    gather.list[0].type = GATHER_LASTPWM_TYPE; // Gather PWM 0
    gather.list[0].addr = &LastPWM[0];

    gather.list[1].type = GATHER_LASTPWM_TYPE; // Gather PWM 1
    gather.list[1].addr = &LastPWM[1];

    gather.list[2].type = GATHER_DOUBLE_TYPE; // Gather Dest axis 0
    gather.list[2].addr = &chan[0].Dest;

    gather.list[3].type = GATHER_END_TYPE;

    gather.bufptr = (double *)0xfffffffffc; // force more than endbuf
    gather.endptr = gather_buffer + 3 * n_Samples;

    TriggerGather(); // start capturing data

    MoveRel(0,20); // Start a motion

    while (!CheckDoneGather()) ; // wait till all captured

    // print all captured data (every 50th sample)

    for (i=0; i<n_Samples; i+=10)
```

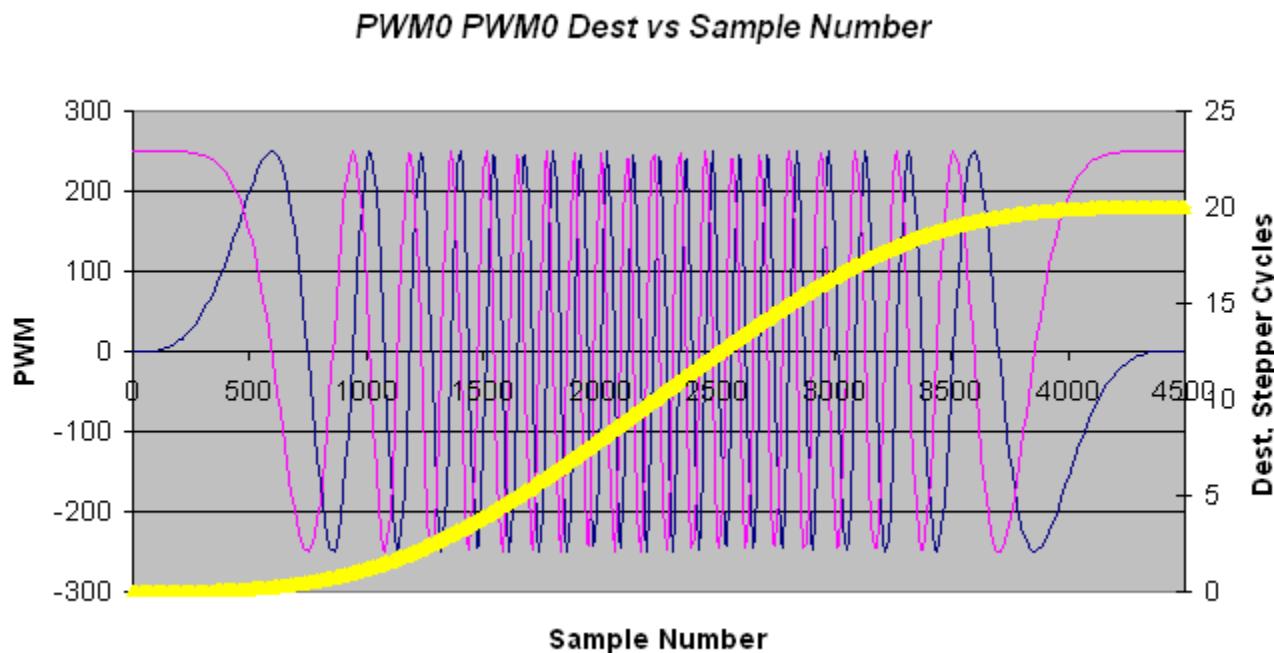

```
printf("%d,%f,%f,%f\n", i,gather_buffer[i*3],  
gather_buffer[i*3+1],  
gather_buffer[i*3+2]);  
}
```

Data will be printed to the **KMotion** Console Screen which is also written to a permanent log file at:

**<KMotionInstallDir>\KMotion\Data\LogFile.txt**

Normally data scrolls off of the Console Screen into the permanent log file, to flush all data into the log file, exit the **KMotion** application.

An Excel plot of the captured data is shown below.
